

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + Beibehaltung von Google-Markenelementen Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + Bewegen Sie sich innerhalb der Legalität Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

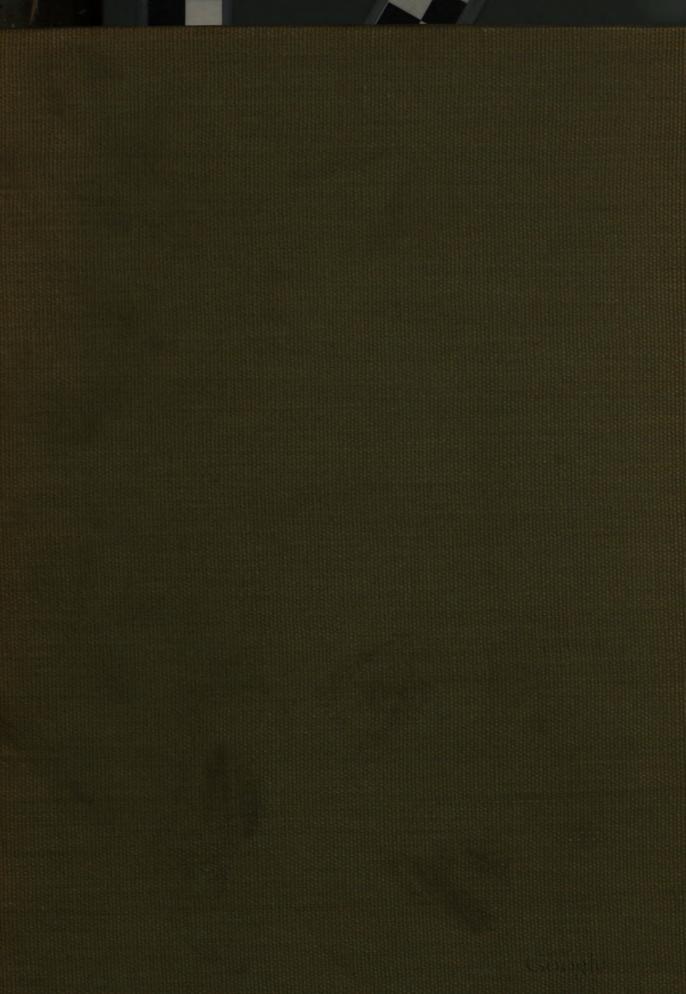

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter http://books.google.com/durchsuchen.

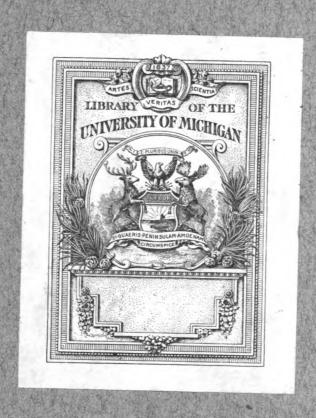

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

Bienna Clinical Lectures.

THE ETIOLOGY OF SYPHILIS MALIGNA.

By Prof. NEUMANN, M.D. Univ. Vienna.

At the Third International Congress of Dermatoarther infra international Congress of Dermatology, held in London, Tarnowsky read a paper on the "Etiology of Syphilis Maligna," which was at that time, and still is, one of the most obscure sections of syphilography. His remarks may be summed up in

six paragraphs:

1. The course of syphilis is unfavourably modified and the disease manifests itself in a severe form when the organism is infected simultaneously with the syphilitic virus and with pyogenic cocci. This mixed contagion may have two pathogenic results which manifest themselves in the primary, secondary,

or tertiary stage of syphilis.

2. When this mixed infection can be clearly diagnosed at an early period of the disease, the characteristic manifestations can be isolated and recorded separately. The primary sclerosis presents a peculiar course from the very beginning, commencing with an acute form of ulceration with a tendency to become phagedænic in character, the latter phase being ushered in by a short period of incubation not exceeding three or four weeks, with a well-marked febrile eruption of polymorphic pustular syphilides re-sembling ecthyma superficiale, rupia, or impetigo and rupia, with dry papules and maculæ. The special feature of these polymorphic syphilides is to be found in the pea-like tubercles forming the inflammatory centres which tend to soften, and three or four days later break down with the formation of pus and débris, leaving a sore that marks the secondary phase

in syphilitic skin affections.

3. These purulent syphilitic tubercles contain staphylococci aurei or albi, which can be detected throughout the whole course of syphilitic condylomata.

4. A simple primary sore, or erosion, with an indurated base and large indolent inguinal glands, having all the appearance of ordinary syphilis at the beginning, may, by exposing the organism to severe infection, so alter the ordinary character of the disease as to give rise to those purulent syphilitic tubercles on the skin which usher in the malignant eruptive disease.

5. As a general rule the so-called deep ecthyma, rupia, and impetigo that occur during the secondary stage of the disease, usually precede the development of the purulent syphilitic tubercles. In addition to these the impetiginous syphilides, such as pustulosa crustosa, or the confluent pustular ulcer of the secondaries, assume a rapidly destructive tendency.

6. These tubercles are not identical with gummatous nodes, which develop early, running a rapid and acute course, but are easily differentiated by their active infectivity. Some doubt exists as to the connection they bear to the first "proruption," or so-called false

gummata, which are also infective.

To this resumé of his paper may be added our actual knowledge on the subject, in that these purulent syphilitic nodules are to be found in the

secondary period as well as in the primary, which is now admitted by Tarnowsky himself, who assures us that the microscope has convinced him of this fact, which, moreover, has been confirmed more recently by Wlajew, Tschistjakow, and others.

A case of this kind, admirably recorded by Tarnowsky, has recently come under my own personal notice. It is, happily, a comparatively rare disease in Vienna, and this leads one to reflect on the difficulties that such a morbid process involve in the elucidation of controversial points. The most salient point in this argument carries us back to the belligerent scenes of the past, and raises the oft-disputed and still undecided question, whether this morbid condition (syphilis maligna) depends on the quality of the virus, or on other factors, such as constitution, idio-syncrasy or greater susceptibility to the syphilitic virus?—all of which are favoured by Tarnowsky's conclusive results. But there is another question equally entitled to a reply when considering this matter, viz., how far do external circumstances influence the course of the disease and transform its character from one of simple syphilis to the malignant forms? Is the virus the same, or is it different ab initio? or have we yet to discover some unknown concurrent factor that differentiates the one from the other?

On studying the course of the disease from the primary invasion to the gummatous stage, plainly demonstrated on the skin, mucous membrane and tissues, none will dispute that the morbid products are due to some syphilitic excitant or toxin. must, therefore, conclude according to the foregoing logic that purulent or ulcerative sclerosis is a special or exclusive product of the pure syphilitic virus, as the pus is produced by a pyogenic bacterium. At the present time we will not pause to consider this pyogenic microbe as it matters little for our purpose whether the bacterium was in the original infection in combination with the syphilitic virus, or is a later

importation,

It is not inadmissible, neither do I deny, that purulent accumulations can be produced by certain chemical irritants independently of pyogenic bacteria, and possi ly this may be the case with the organic virus of syphilis. The latter assumption must be accepted as purely speculative, and is would be hazardous to place it on the same footing as the demonstrated fact of a pyogenic microbe being present which must have been introduced ab initio, or during

the progress of the disease.

We must, therefore, conclude that this product is the result of a mixed infection of syphilitic virus and pyogenic virus, and that every purulent sclerosis

is a mixed centre of this infection.

Now daily experience, teaches us that the greater number of these purulent sclerotic cases run the usual course of the disease, and are seldom followed by the malignant form referred to. It must also be patent to every observer that the pathogenic element of syphilis, and the pyogenic cocci, or mixed infection of Tarnowsky, per se, do not alter the usual course of the syphilitic virus, or by their combined presence invariably produce the dreaded form of syphilis maligna, otherwise the disease would be more prevalent than we usually observe it to be. We consequently must conclude that some other factor, or factors, must be sought for to explain these rare individual cases of such interest and importance.

From these conflicting deductions on the origin of malignant syphilis, we are forced to exclaim in the words of Jullien, "Il est peu probable qu'il faille accuser en pareil cas la nocuité particulière de la graine virulente," a general e pression used long ago and just as applicable to-day, with regard to the nature of the virus as it was in his time. We are thus compelled to admit that a purulent sclerosis exists in both malignant and simple syphilis, that on the inception of the former the virus implanted is more individually severe on the organism, and when favoured by external influences the malignant condition is induced terminating fatally. Tarnowsky acknowledges this in his arguments, although he attempts to prove that the association of the pyogenic cocci must be present, and adds that alcoholism, duberculosis, scrofula, scurvy, diabetes, or other tebilitating conditions of the system tend to affect the virulence of sypailis, and increase its intensity. Daily experience also proves the converse, viz., that many very severe cases of syphilis by careful treatment, and hygienic attention are converted into a simple and benign character, which otherwise would, in all probability, have proved malignant. There is another point in Tarnowsky's arguments that is in conflict with experience. His teaching is that if one be infected with a benign virus of syphilis the course of the disease must necessarily be simple. Now the obverse of this is the daily experience of every syphiloligist, viz., that infection form a simple case may assume a very virulent type, and even terminate in the malignant form.

Tarnowsky records another peculiar condition very commonly observed that, although the dry sclerotic or papular form, has no pyogenic bacteria in the early stage, yet a pustular eruption follows. Now, if the primary quality of the syphilitic virus indicated its virulence, the manifestations of the future reaction on the organism should appear in some definite form thus indicating the potency of the toxin and its attributes on the organism in presenti et pro futuro. If, for example, a patient be infected with benign syphilis, and pass on to ulcerative sclerosis, while a second patient, infected from the same source runs rapidly into a phagedænic sore with lymphangitis and euormous swelling of glands nothing can be discovered in the source to differentiate these two cases; the bacteriology is the same, pyogenic cocci being found in both, and both may have a favourable

termination.

This plural connection of wirus and cocci in the primary stage of syphilis is admitted by every careful observer, yet Tarnowsky's results are invariably absent. All are cognitant of the dangers that may possibly arise when the products of mixed forms are thrown into the system, as "papules in the mouth are prone to produce pyogenic bacteria" "the fissures on the tongue are often covered with a grey purulent coating from pyogenic cocci" which are acknowledged to be severe complications. Many other authors, such as Hallopeau, Jaenseline, &c., have demonstrated this pyogenic combination in the nose and pharynx, as well as the purulent dermatose condition which they have ingeniously designated "Biopsia," but none of them have been able to come to conclusions in favour of the view that these multiple centres are all malignant, nor do they believe in two pathogenic causes, the one benign, the other malignant, because very few of the cases assume the latter unpropitious properties.

Before this question can be settled several answers are necessary. We are forced to admit that the product of this mixed infection is largely affected by

external circumstances. If no pyogenic bacteria are found in the organisms from the centres of invasion by which syphilis is known to enter; can we confidently say that the organism is perfectly free from malignant syphilis? No affirmative reply can be vouchsafed, because no positive proof is forthcoming to establish the presence or non-presence of the pyogenic cocci in the original virus. There are, however, individual cases which become malignant. while the greater number do not though inoculated with the same virus. Why should the former become pyæmic while the latter are exempt? I think we may safely conclude that there are external conditions which modify, and so alter the course of the disease as to transform a simple into a malignant case; and the most powerful of these external agents are alcohol, tuberculosis, diabetes, malaria, &c. These again can be so modified and altered by therapeutical and hygienic measures and by condition of environment, and mode of life, as to obviate the malignity of very ominous and threatening cases.

Tarnowsky, though strongly advocating his pyemic theory, makes a few assertions in his concluding remarks, which would lead us to believe he has very little faith in his own hypotheses. He tells us: "the problem of mixed infection is not yet conclusively solved." "All the elements of purulent syphilis with their conditions are not yet sufficiently known," while he admits that chronic alcoholism acting in the blood-vessels of liver, kidneys, &c., may pervert very innocent cases by checking elimination, and thus lead to imprisonment of the pyemic infection, and its products, thus intensifying the

syphilitic virus.

We have yet to prove that the pyogenic bacteria of syphilis maligna constitute the principal factor in the production of this intractable disease. They are admittedly associated with the malignant state; but how far the pyogenic bacteria are entitled to be regarded as an etiological cause, it is at present difficult to determine. Pending the discovery of the potent factors that govern the disease, Tarnowsky merits our best thanks for the suggestion of an early introduction of the pyogenic germ before pustular eruption or efflorescence. Though largely hypo-thetical, his view is rational enough, but it proves fallacious in practice. The susceptibility of this mixed infection must also be influenced by the disposition of the individual; in one it may be intense, while another may experience little of its action, and this, moreover, may even be only temporary in its duration. The precocious cases, i.e., where later forms appear among the early symptoms, running a fulminating course with a destructive tendency, and having the pyogenic bacteria, have no pathognomonic indication to prove the malignancy; but other hypothetical factors added on to these conditions forestell grave results. The syphilitic virus, combined with pyæmic infection, is undeniably a severe form of common syphilis, but it carries no assurance that it will in future become malignant.

In the tertiary stage of syphilis the purulent discharge is profuse, from sores on the rectum, genitals, gumma, &c., with frequent toxic erythema multiforma, yet the formation of pus usually ceases, and the discharge ultimately resumes its normal character. Fournier affirms that sores in the pharynx with pyogenic cocci, and great disturbances of tissue pass off as simple sores without any apparent invasion of pyæmic symptoms, and all this tends to prove that certain unknown factors must be associated with these specific conditions to produce the malignant result. Experiment on dogs with thermic, mechanical and chemical irritants in combination with different bacteria have failed to produce the malignant result. Wurtz and Hudel's experiments, especially with alcohol, equally failed to produce the desired

result. It follows that the individual specific reaction of the tissues is influenced by the pathogenic operathe disease is inductive by the pathogenic opera-tion of the several factors, and that the pathogenic bacteria and purulent processes are mere incidentals occurring in the progress of the disease. We may, therefore, conclude that early severe symptoms of syphilis do not form essentially characteristic phenomena of syphilis maligna; neither can we prove that rapidity of course or phagedænic tendencies will always lead to pyæmic intection.

TWO CASES OF

PERFORATION OF THE UTERUS DURING CURETTAGE.

By GEORGE ELDER, M.D.,

Vice-President, British Gynsecological Society, late Senior Surgeon to the Samarıtan Hospital for Women, Nottingham.

In the November number of the Medical and Surgical Review of Reviews reference is made to several cases recently reported of uterine perforation by sound and curette, and also of a case where apparently an unduly patulous Fallopian tube caused a simulation of the accident. In addition, two cases of apparent perforation are quoted from Bentauer (Centralblatt fur Gynecologie No. 42, 1897), which he endeavours to explain on the assumption that occasionally during manipulation the uterine muscle becomes so relaxed or so elastic that it readily yields to the pressure of an instrument. These and many other cases related in various journals and recent books on gynæcology (notably in Kelly's "Operative Gynæcology," Vol. I., p. 479), which proved that the danger of perforation of the uterus is not so rare as generally is imagined, and that occasionally it is followed by fatal results, prompts me to give my own personal experience of the accident, more especially as I have heard a very eminent gynæcologist scoff at the possibility of a sound perforating the uterus, a state of scepticism which, when it finds expression in speech or writing, is apt to give an impetus to the already too frequent and incautious use of instruments.

My experience is limited to two cases which, curiously enough, happened within a few weeks of each other.

The first occurred in the person of the wife of a medical man in the country, who was suffering from persistent metrorrhagia after a premature birth, which rest and the usual medicinal remedies had failed to check. The patient was a young, healthy woman—the mother of two children—and with no record of previous uterine mischief. Ether was given by my late colleague, Dr. Truman, and as is my custom I examined the uterus bi-manually to ascertain its size, direction, and freedom from tubal or ovarian inflammatory mischief likely to contra-indicate instrumental interference, and then dilated with Hegar's dilators. This was quickly and easily done and a blunt curette introduced when, to my astonishment, it passed in without any sensible obstruction until all but the handle had disappeared. A sound penetrated in the same manner, and the point of it could distinctly be felt under the abdominal parieties. Beyond packing the uterine cavity and vagina with iodoform gauze nothing further was done, and to my relief convalescence was smooth and uneventful

The value of dilatation alone in such cases was shown by the patient having no return of the uterine hæmorrhage. A few weeks afterwards Dr. Huthwaite, lately of Sandiacre, near Nottingham, and now of Skipton, asked me to curette a young woman for post-puerperal endometritis. Coming so soon after the other, even more than the usual care was taken in dilatation, and, just as in the previous case, the curette

had hardly been used before the same accident occurred. To prove the matter beyond a doubt, a piece of powel presented in the cervical canal. This I replaced and packed the uterine cavity and vagina, as before, with gauze This patient also seemed none the worse for the perforation and recovered well.

In both of my cases I am disposed to believe that the damage was done by the dilator and not by the curette, inasmuch as curettage had barely commenced

before the perforation declared itself.

Curettage has now become so well established in the treatment and diagnosis of intra-uterine troubles that one is apt to lose sight of its dangers and adopt it, when other and safer procedures might be substituted. It is well known that the uterine walls are noftened and thinned by recent abortions or labours at term, by sepsis. and by cancerous, sarcomatous, and tuberculous degeneration—conditions most exposed to injury from instruments—and it is just in these cases, whether for the removal of decidual remains or the clearing up of diagnostic doubts, that digital exploration is of service.

Adopting this method would greatly limit the need for curettage, and in the latter event the risk of accident is much diminished by a preliminary bi-manual examination of the parts to ascertain the condition of the appendages and the direction of the uterine body. The selection of a means of dilatation, is of great moment. Tents for this purpose on account of the danger of sepsis are, I take it, now

almost obsolete.

On account of their tendency to tear the tissues by reason of their shape, I have recently discarded Hegar's dilator for a modification—conical shaped—instead of cylindrical; and more finely graduated. Unless for scraping away malignant tissue, I always use a blunt curette.

Now, with regard to the treatment of perforation, assuming that all needful antiseptic precautions have been taken before and during the operation; the packing with iodoform gauze is, it seems to me, the best, leaving graver operations, such as opening the abdominal cavity, and suturing the rent or removing the septic uterus, for future consideration should the symptoms point towards them

It is only in a very small minority that such occasions will arise.

THE SMOKE QUESTION

By ROBERT LEE, M.D.Cantab., F.R.C.P.Lond.

Late Chemical Scholar of Caius College Cambridge; and Lecturer on Forensic Medicine and Pathology at the Westminster Hospital, &c., &c.

THERE is no doubt as to the smoke question being one of great interest to all members of the medical profession, and one that can be better discussed by them than by any other class of educated men. It is a question which requires some knowledge of chemistry, of physics, and of physiology to enable us to deal with it properly. To understand how smoke is produced, in fact to answer the simple question, What is smoke? is not as easy as may be thought; and it must be answered before we can hope to prevent smoke. We have also to understand the physics of ventilation, a subject by no means simple, but on the knowledge of which the construction of our chimneys and firepla es depends. The architect cannot be expected to know very much of either the chemistry or physics of the smoke question; and as regards its physiology, the public must come to Officers of Health, those who have made sanitary science a matter of study, and to the medical profession generally for an opinion on the injury done by smoke.

If we wanted to explain this matter to anyone who

Digitized by Google

knows nothing of chemistry, physics, or physiology; and many are in that happy state of ignorance; we could not do better than take a common paraffin lamp and light it, and ask our pupil to look at the smoky flame when there is no chimney on. And if we slowly put the chimney over the flame we show how the flame becomes brighter as we lower the chimney, and at last when it is fixed the smoke has disappeared, and the flame burns bright and clear.

That petroleum lamp, when it is lighted, is rather like a living animal. It must have air, pure and abundant, if it is to burn well. The chimney provides this air, and the way in which it brings air right into the flame, and thus supplies it with the oxygen

it requires to make it burn properly.

We can go on and explain how it is that smoke is produced when anything is ignited and burns. If the combustion is perfect there will be no smoke; and perfect combustion is the result of proper combination of the carbon of which the substance is composed, with oxygen, so that these elements unite and form carbonic acid and carbonic oxide gases, and no smoke is occasioned.

But if some of the carbon escapes, not united, because it is not supplied with oxygen to form one of the gases, the result is smoke. The question then of how we are to get rid of smoke, reduces itself to the problem, how can we supply air or oxygen in such quantity that no carbon can escape free, ununited with

oxygen.
When we try and treat an open fire in an ordinary grate, much in the same way as we have treated a petroleum lamp when we put the chimney on, and get a bright flame, we may succeed in preventing the

smoke which coal usually produces.

But there is a great difference between different kinds of coal when being burnt. Some will produce smoke very easily, and some, such as anthracite, will not burn unless then have a good supply of air.

The question we have to consider is how our fireplaces or grates can be constructed so that they may ensure the proper combustion of the fuel we are using, much on the same principle as the chimney of the paraffin lamp secures the proper combustion of the oil. If we take a glass chimney and cut away two or three inches of the lower part, so that the burning wick on one side is not covered in, we find that smoke is produced on account of air passing over the flame and not through it. In our ordinary grates the space above the bars is so great that smoke is inevitable.

Now, there is a curious fact which is known to very few, and that is that a great deal more air passes through the top of the open part of the grate than over the top bar. This is best shown by holding an anemometer just above the top bar when a fire is burning, and then raising it slowly straight up towards the top. We often find that the anemometer does not register more than 10 or 15 feet per minute just above the top bar, but at the highest point it registers 250 or more. The reason of this we will not now discuss, but we can see that the chief point to attend to is the prevention of this passage of air above the fire instead of through it.

If we wish to prevent smoke and obtain perfect combustion of fuel we must in some way lower the chimney and bring it down towards the top bar. Of course we can do this by putting on a blower. The effect of the blower is to cause air to pass through the fuel. By this, the combustion of the fuel is greatly increased and the draught up the chimney is more active. We do not gain anything, however, by the blower, as the increase of heat is only expended in making more draught, and not in making our room warmer. We must in some way prevent the heat from escaping so rapidly, and this can only be done by a damper or something to arrest the passage of the heated air. If we calculate carefully the size of

the blower and the damper and use these two properly, we can prevent smoke and save about half our coal.

When we compare an open fire-place to a closed stove, we can appreciate the advantages and disadvantages of each. The open fire-place is a good ventilator, the closed stove is a bad one. The open fire-place causes great loss of heat, the closed stove is the great economiser of it. The one is healthy, the other is unhealthy, so far as ventilation is concerned. It is probable that if we can obtain a medium between these two we may safely go, in medio tutissimus. It is probable that this medium will soon be found, if it is not already thought out; and if the science of our fire-place is understood, any method proposed to us may be fairly criticised by those who understand why smoke is caused and how it can be prevented.

The Marbeian Lectures, 1898.

ON DISEASE AND ITS TREATMENT

AND THE

PROFESSION OF MEDICINE IN THE

YEAR 1899. (a)

By WM. EWART, M.D., F.R.C.P.,

Senior Physician to St. George's Hospital, and Joint Lecturer on Medicine to the Medical School; Senior Physician to the Belgrave Hospital for Children.

LECTURE III.—EDUCATION AND MEDICAL PRACTICE.

OUR attention is claimed to-day by the Medical Profession, its labours, its difficulties, its prospects, and its rewards; but the future of medical education and some questions of practice bearing upon our status will be

dealt with more prominently.

The lateral pressure from which we have suffered will probably be relieved for the growing generation. The world is expanding at a rate for which there is no parallel in history. An entire continent has not only been explored within a few years, but is being wired and railed, and the machinery of civilization called into existence simultaneously at many centres. China may soon offer a field where the English physician may come into fashion. The colonies, especially those where gold is the attraction, are only beginning their period of expan sion. But we must realize that Canada, Australia, and New Zealand are no longer dependant upon home supply. They are now medically self-supporting; the pupils of their universities come home for the study of special subjects and to watch our clinical practice, but they are already fully qualified, and their numbers are sufficient for the local needs.

Our worst pressure has been from below, and to this we shall presently revert. From above our limitations arise from too much or too little legislation. Of late instances have not been wanting in which the unreason-ing opposition of the uneducated vote, or that from noisy or hysterical sections has been brought to bear against us with the sanction of the law. Thus some of our professional events have been retrograde. I need not dwell upon achievements such as the ticket-of-leave given to small-pox and syphilis, and the setting back of the clock of experimental science.

These evils were avoidable. Fortunately they may yet be remedied, but for the loss of irrevocable time. Compared with the dealings of those well-ru ed nations, whose progress is not allowed to swerve from common sense, and who follow a straight road to any social object, in this country we are, thanks to those manœuvres, left hopelessly behind, electing to follow where we might lead. These risks and delays are the sport which delights a free

people, and in favour of which it can only be said that by (a) Lecture delivered before the Harveian Society of London, Dec. 15th, 1898.

way of compensation it perhaps keeps us active and in fighting condition.

Other reforms are of our own making; they bear upon medical education and examinations, and upon the rules which govern our mutual relations and our relations to the public and to the State. Well considered and measured to suit the times, they may not always be adapted to meet all future needs. But they cannot again be modified until after a period of friction which makes us long for the next change, and yet dread the unknown complications which it may cover.

PROFESSIONAL ALTRUISM AND SELF-SACRIFICE.

To practice medicine is to learn that our lives belong to others rather than to ourselves. There is an unconscious and passive altruism in the lives of most men; they are unaware that they are wearing themselves out for the sake of their fellow men. Our altruism is both conscious and intended; it is an active altruism. It would be difficult to find a more striking sight than that of a whole profession working strenuously for the sake of its fellow-creatures, at the systematic destruction of its own means of support. Is any disease voluntarily allowed to survive in the individual or in the community, any contagion given free scope, any sanitary defect left unobserved and uncorrected, any oppressive or dele-terious conditions of labour allowed to proceed unchecked? It is left for others outside the profession to marshal every resource of ignorance and prejudice for the purpose of keeping alive fatal diseases.

The same unreckoning policy has led us to instruct our patients in practical matters of health. Institutions have been multiplied over the country, every opportunity being utilised to spread among the public an ample knowledge of the arcana of medicine; and with the same view medical writers are now lending their pen to the

But there are limits beyond which generosity itself ceases to be wise, and fails in its purpose. The quality of work deteriorates when, instead of strengthening, it wears the labourer; and to avoid this is of importance, not alone to the profession.

While the earnings of other workers have been rising with the general increase in our national prosperity, the reverse has happened with us, and events have brought about difficulties for which none can be held responsible. All sections of the profession have felt them, each section imagining itself to be the only one to suffer.

To put the matter briefly, there are, perhaps, not too many medical men, but whilst there might be work for all, this is neither properly apportioned nor paid for. Of the two chief contributory factors, the over-crowding of the profession is, to my thinking, the least. But the opportunities for practice have been restricted by science and by charity. And it is now manifest that by seeking some relief from their difficulties in the provident system, individual members have helped to restrict the supply of employment for the profession.

THE PROVIDENT SYSTEM AND ITS PROBLEMS.

In its ideal form the provident system seeks to secure the greatest good to the greatest number, benefiting alike the deserving poor and the profession. Its principle is the insurance of the healthy against the expenses of future illness. That principle has been accepted by the profession as belonging to our scheme of usefulness, and as tending to professional advantage if only it were fairly worked. Our services are for many a necessity, and it is right that they should be within the reach of those for whom they are intended.

The poorer patients have five courses open to them:
(1) Some of them are sufficiently near the margin of pauperism to enable them to obtain Poor-law relief (2) Many of them apply to the chemist for advice and medicine, and this largely keeps up the practice of counter prescribing. (3) Others are anxious for treatment by hospital physicians and surgeons, and endeavour to obtain it at the hospital for which they have a predilection, though this may not be the nearest one to their own home. (4) A large number enrol themselves in the lists of the provident dispensaries and of the clubs. (5)

Others prefer to get their advice independently, and at the time when they think they need it. If the medical man's charges should be prohibitive he would drive this humble practice into the other channels which have been indicated. In order to meet the necessities of the case there must be for his advice a sliding scale within the reach of the humblest means. This unavoidable smallness of remuneration is a reason for his preferring a system where it is to a certain extent disguised. Unfortunately the slender compensation so well deserved has been only partially reaped by the profession. Benevolent in its intent, co-operation has opened the door to novel dangers and abuses of which the practitioner is ultimately the victim.

The Provident Association.—The beneficent institutions known as dispensaries seek to be self-supporting; but a charitable interest is taken in their management by members of a richer class, and this is a saving clause, for much depends upon the spirit of those who administer as well as of those who receive the relief. The collateral advantages which are opened up to those who serve a well-conducted dispensary render it a matter for regret that it has not been found practicable to extend them to all the local practitioners, or at least to as many as may wish to participate The remuneration itself is small. but it is fairly divided according to the work done.

The difference between these institutions and the friendly societies is fundamental; in the latter the softening element of charity is less prominent, and that of sentiment is not included. In early days the medical man's willingness to help them may have been considered a favour. This is now changed, and they have not always refrained from turning his difficulties to account. Other associations, built purely upon the principle of commercial insurance, although business-like in some directions, are free from any scruples connected with medical etiquette, and in other directions there is less regard than in the friendly societies for the individual interests and for the professional dignity of the medical officer.

THE PREVALENT ABUSES.

The defects which have arisen are clearly unintentional, and the outcome of ordinary economical principles. They include: (1) The obviously inadequate remuneration for excessive work and responsibility; and (2) the unjust appropriation of advantages intended for the poor by those able to pay.

Were the charitable ministrations bestowed only on the deserving poor, their cost would be a lighter burden. But it is well known that, owing to imperfect checks, and to the failure to realise the fault of which they are guilty, many thoughtless individuals receive relief who are really able to pay a fair honorarium for private attendance, and this is contrary to the intentions of those who manage these institutions.

This abuse is not sufficiently guarded against in the organisation of clubs. Some men of substance are admitted as members, or retain a membership assumed in less prosperous days, and do not refrain from getting their medical advice at an almost gratuitous rate. The practice of others is made to suffer besides that of the medical officer, for should he fail to meet cheerfully the behests of his employers, or refuse to submit to a reduction, the club may find a stranger to fill his place, and this will mean additional competition in an already restricted field of practice.

The worse troubles arise in connection with the medical aid societies. They actively canvass the public. Their medical officer is advertised—not always fairly, it is said—but he may have to suffer for the advertisement. And the climax is reached when he is victimised not only by the societies but by intermediate agents Instances have often occurred when agents have induced people to ensure, and to transfer themselves from the private list to the club list of the same medical man,

The Detriment to the Profession .- Diminution in practice goes hand in hand with a lessened value set upon professional services. But the worst aspect of the whole position is the further decline in dignity and emolument due to the fact that, small as may be the pittance, it has its market, and any competition can only lower its figures. The low value which is thus forced by contract

Digitized by GOOGLE

reacts upon the remuneration of others, who but for this would have been in a position to resist the unmerited depreciation of their services. Thus special correctives are needed against the evils known as the tyranny of the clubs, the lowering of the fees by competition, the exploitation by medical aid societies, the underselling of medical work, the insufficient wage limit, and also the admission of women and children at a lower subscription than men, though they need more attention, and previously contributed to private practice.

THE REMEDY.

Where is the remedy to come from? Its possible sources are: State interference, corporate action, independent combination within the profession, which might be purely local or more general and education.

Some action has already been taken, especially in the direction of local combination. Much credit is due to various local groups for their energy and success, and their example may tell at a distance. Indeed, it has suggested the idea of an extended combination, which might include representatives of all local associations, and through them of all practitioners interested in the provident system.

A totally distinct action has also been proposed, that of State aid in this difficult matter. This is a remedy not without a danger, for if the State is to come to our assistance it is possible that its inelastic control might fall heavily upon us, and trammel us, when it would be

much to our advantage to be free.

But leaving State control aside, their remains the official action of the professional governing bodies, who alone can speak for the entire profession. If I mistake not, there is a strong feeling abroad that these difficulties should be noticed officially; but others are inclined to think that the profession ought not to be committed, and that independent combination should be able to provide a remedy.

Between courses so different it is difficult to choose. One of them pledges the profession, the other allows free scope to self-government without the assumption of too

onerous a responsibility.

Self-help is sound policy, but in this matter it is regarded with good reason as unequal to the task. There is a difficulty in repudiating arrangements firmly rooted in localities; and any efforts in that direction are but too likely to be defeated by the action of members of the profession who are outside these local combinations. meet this difficulty, it is not to be wondered at that the General Medical Council should be appealed to for an exercise of their power to approve those arrangements which have been found most suitable in the various districts, and to restrain registered practitioners from an unprofessional intrusion which tends to render joint efforts nugatory. This would doubtless afford the easiest way out of the present complication, provided it could safely be resorted to without prejudice to future advantage. It must not be forgotten that a march has been stolen upon the profession owing to too isolated action, and it is to be feared that the local combinations must remain hampered by the influence of these unfortunate beginnings, and that their proposals might not come up to the level which the profession may have in prospect when the time comes for corporate and truly representative action. In view of that object it might be undesirable that the profession should stand committed to any adjustment arrived at locally or even by a combination of many local groups. Indeed, there might be a danger lest any larger combination might wear in the eyes of the public an importance other than that which it claimed for itself, and be thought to carry a mandate from the profession. In this respect there is perhaps an advantage in combination preserving for the present its purely local character.

The Reasons for Delay.—In favour of a policy of wait-

The Reasons for Delay.—In favour of a policy of waiting the fact should be remembered that we are still within the period of transition, and that we cannot yet foretell the proportions which the co-operative treatment may ultimately attain. One point appears to be clear. Any final settlement should be made on an independent basis. A privilege usurped, however unintentional the usurpation, is not from the standpoint of the injured party a fair basis for negotiatior. All local attempts at

readjustment must suffer from this disadvantage. It must be made evident that the profession repudiates the estimate which has unfortunately been placed upon the value of the services of its members. Though I may not have much support in leaning towards cautious delay in any comprehensive handling of the difficulty, I feel sure that I am with all of you in thinking that its study cannot be safely postponed, and that it should engage the earnest and early attention of our authorities.

The Remedy from Education of the Public and the Profession.—There is a different remedy, most effectual, but slow—the teaching and the appreciation of that which we owe to ourselves and which is due to us by the public. On onr side, the great body of the profession are guided by those high principles which are being universally taught. The dangerous few must be either educated up to its level or kept out.

It is difficult to overrate the influence which can be exercised on the minds and dispositions of our pupils whilst they are passing through the medical schools. More may be done perhaps to raise in their youthful mind a superior ideal of the dignity and of the unity of the profession. Men cast in this mould might be allowed to shape the higher interests of the profession

wherever they go.

Much more general is the lack of due appreciation on the part of the public, especially among the lower classes, who are not unlikely at times to misinterpret the most charitable intentions. Literature might do much to enlighten them as to our position; and in the recent lofty achievements of the profession there is a theme which, if properly handled, might work in the direction which is wanted.

The remedy would thus consist first and foremost in the cultivation of a high ideal in the study of medicine, and, in the second place, of the authoritative influence which combined action might exercise upon the Press.

MEDICAL EDUCATION.

Examinations are a necessary evil. The public must be protected, and a mass of important facts must be grasped by the student. But under this load the freedom both of study and of teaching suffers, and imagination and original thought are less developed than memory. We have recently heard from authorities that the burden of scientific facts is becoming intolerable for the student of medicine, and that some part of the burden must be removed; and, in anticipation of a yet distant revision, it may be permitted me to bring forward impressions gathered from some observation of the student and of his work, especially in their clinical aspects.

Clinical work is for us all essential, and the difficulty is how to give to its study a share not altogether dis-

proportionate.

The Preliminary Examination and the Recruiting of the Profession. In the students own interest, our gates should not be thrown open too widely, lest he should be caught in a groove, in which, as time wears on, he may find neither success nor escape. Medical students need not be picked men, but tried men they should be; and to ensure this is the chief office of the entrance examination, which might also be a means of checking an excessive supply

Our opportunity is to frame an entrance examination which should test men as to their fitness for their future labours, but should not demand of them anything wasteful from the point of view of their life's work. On the contrary, the entrance examination might be rendered practically useful in the direction of relieving as

much as possible the overloaded curriculum.

The utilitarian reform which we have witnessed seems to have stopped short at the sacrifice of the classics. Yet there are studies now neglected in the curriculum, the rudiments of which should not be entirely unknown to members of a learned profession. I refer to the elements of botany, of zoology, and of geology, which are nost desirable. If made compulsory in the schedule of the Preliminary Examination, these subjects, together with physics and chemistry, would be useful to the student, and educationally they would be some compensation for the loss of a classical training

The Curriculum.—The greatest improvement in medical

Digitized by Google

education is the recently introduced five-years' curricu-This extension has already produced the best results. Yet much pressure remains, and the question has been asked whether the best use is made of the additional time, and whether a special claim could not have been established in favour of our professional training, so long and increasingly sacrificed to the preliminary subjects.

The old-fashioned apprenticeship was given up long ago without any equivalent as a substitute. It is impossible that we should ever return to it. Yet it was a thoroughly practical though primitive method of learning as much of the profession as the local opportunities allowed. In that arrangement the supply of scientific knowledge was scanty, but there was little waste from the point of view

of utility.

This distribution of the student's work has been come pletely reversed, but the partial sacrifice of the practical professional studies was an unintended result, due to the desire to cultivate a higher science in the service of medicine. Unfortunately, for a long period the teaching of the sciences had to be theoretical and by lectures without any practical participation on the part of the learner. Thus the student, deprived of the apprenticeship, spent his early days in studying practical science in an unpractical way. When he joined the country practice as a qualified man it was the old apprenticeship over again—most things practical yet to be learnt—only the apprenticeship was at the wrong end of his time.

(To be continued)

Clinical Records.

Case of Fibroid Tumour Complicated with Pyo-Salpinx Removed by Sub-Peritoneal Hysterectomy. (a)

Under the care of Dr. J. MACPHERSON LAWRIE.

Mrs. S., set 40, consulted me on October 21st on account of excessive abdominal pain, which incapacitated her from her duties, and a swelling occupying the right side of the abdomen. On examination, the swelling was accounted for by a fibroid tumour of the uterus, and as her sufferings were great, an operation for its removal was advised. This took place on November 6th. The tumour was exposed by a long incision, and found to be complicated with a pyo-salpinx in the right side. Both appendages were diseased, with numerous adhesions, and completely matted to the surrounding parts. The tumour itself was firmly adherent to the great omentum. as well as to the bowel and appendix, and considerable trouble was experienced in the process of separation. The broad ligaments were then divided externally to the ovaries and tubes, and the uterine arteries secured. The overies and the derine are refers secured. The cervix was divided by a wedge-shaped incision, and brought together with catgut. The peritoneal flaps were laced across the pelvis and over the stump. After careful sponging, the abdomen was closed without flushing or drainage.

Patient made a good recevery.

Case of Fibroid Uterus undergoing Malignant Degeneration Removed by Vaginal Hysterectomy. (a)

Mrs. F., et. 29, consulted me on September 9th, 1898, on account of severe continual uterine hemorrhage and leucorrhœa for two years, accompanied by violent pain. On examination the uterus was found much enlarged, and a polypus about as large as an orange presented at the os.

On September 25th the uterus was dilated and the polypus removed. This gave room for a more complete investigation, and disclosed the presence of another swelling occupying the fundus and bulging into the uterine cavity. The capsule was freely divided and a soft tumour shelled out. This was sent to the Clinical

Research Association for examination, who reported that it consisted of malignant tissue.

The uterus was accordingly removed on November 13th by vaginal hysterectomy, the ovaries and tubes being

(a) Cases read and specimens shown at the last meeting of the British Gymecological Society.

taken away at the same time. The patient made an excellent recovery from both operations, and is now in good health.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, DECEMBER 2nd, 1898.

J. A. Scott, F.R.C.S., in the Chair.

SOME RECENT X-RAY WORK.

Dr. HAUGHTON drew attention to the recent sucesses of the process in regard to normal changes in bone structure as well as in congenital and acquired deformities of bone, in diagnosis, prognosis, and treatment of fractures and their sequelæ, dislocations, epiphysiary separations, diseases of bone in dentistry, and especially in the localisation of foreign bodies.

Dr. Scott considered the reducing to figures the comparative lengths of exposure of different tissues was very

interesting.

Dr. LANE JOYNT said that the question of causing dermatitis was most important, but he thought a good deal of false blame had been laid to the charge of the X-rays; he himself had never seen a case of dermatitis from this C&1180.

Dr. E. J. McWeeney asked what effect caseous and calcified material had upon the rays? Also what amount of opacity calculi of different kinds had? Was it possible to get shadows from those soft cholesterin and cholesterin pigmentary calculi found in the gall-bladder? He had seen some X-ray photographs of tuberculous subjects in which the bones showed a remarkable amount of transparency, which might be due to the anatomical fact that the spaces in the cancellous tissue were larger than normal or to a smaller deposition of lime salts.

Dr. MAUNSELL asked whether in the skiagraphs of Pott's fracture the author had found that the astragalus

was dislocated slightly backwards as well
Dr. Knott remarked that at the last meeting there were two specimens illustrative of the fact that the olecranon normally had two, and sometimes three, centres of ossification. In cases of epiphysiary disjunction the solution of continuity always ran through the bone near the cartilage.

Dr. HAUGHTON, in reply, said that he had been unable to obtain any good photographs of tuberculous consolidation in the apex of the lungs owing to the movements of respiration. Caseous material was rather transparent, considerably more so than pus, the latter being nearly as opaque as water. In calcareous deposite very considerable opacity resulted, as the calcareous salt considerable opacity resulted, as the calcareous salt contained lime whose atomic weight is about 40, and the higher on the atomic scale the greater the opacity. Phosphatic calculi were rather transparent, ovalic were the most opaque, and uratic intermediate. Cholesterin the most opaque, and uratic intermediate. was extremely transparent. Regarding the relative transparency of tuberculous in comparison with normal cases, strumous subjects were often found with very transparent bones, probably due to a condition of mal-nutrition. There seemed to be possibly a smaller deposition of lime salts, perhaps associated with an enlargement of the cancellous tissue; but he himself thought the cancellous tissue presented a normal outline, while the transparency was greatly increased. In reply to Dr. Maunsell he said he had not observed dislocation backwards in Pott's fracture. In X-ray photographs he had not been able to establish more than one centre of ossification for the olecranon.

RUPTURE OF ASCENDING AORTA.

Dr. MAUNSELL read the notes of a case of "Multiple Aneurisms in a Young Woman," and showed the specimen. The woman was set. 37, married, and gave a history of having dead born children, which suggested syphilis. The aneurisms were two fusion dilatations of the thoracic aorta, and a sacculated dilatation of the celiac

The latter was the only one diagnosed during life, and its clinical history was very puzzling, as in many ways it simulated a pyloric growth. The woman died of syncope three weeks after coming under observation.

SPONTANEOUS RUPTURE OF FIRST PART OF AORTA.

Dr. J. Lumsden.—The young woman (set. 23) from whom the specimen was taken was brought dead into Mercer's Hospital in June, 1898. She was evidently in the act of lifting a heavy box when she suddenly dropped dead. On opening the thorax the pericardium when incised was found to be quite full of clots. A small linear rupture, which just admitted an ordinary cedar pencil, was discovered at root of the ascending aorta on its anterior aspect, immediately above the anterior sinus of Valsalva. When the interior of vessel was examined a rent was found in the aortic tunics, commencing just above junction of right and left posterior aortic cuspus, encircling the aorta parallel to free margin of the valves, about 1½ inches in length. Except at the point of rupture in front only the intima and media were apparently involved in the rupture, and, doubtless, had not the outer coat given way anteriorly a dissecting aneurism might have resulted. Macroscopically there was no evidence of any extensive degenera-tion of aortic walls, or, indeed, of the heart either, but a few small opaque yellowish-white superficial and irregular patches in the endothelium and subendothelial tissue were to be seen. They projected slightly above the surface, and could be rubbed off in places from subjacent layers, which presented a normal appearance. There was no dilatation of the aorta, and no evidence of valvular lesion was to be found.

ANEURISM OF ASCENDING ARCH OF AORTA EXTENDING INTO LUNG.

Dr. W. J. Thompson.—The patient was a man, æt. 45, a builder's labourer, who was admitted to Jervis Street Hospital on November 13th, 1898. He was carried in by the police in a collapsed state, having had a severe attack of hæmoptysis while walking along the street. The upper part of the right lung, as far down as the fifth rib in the nipple line, was dull on percussion, no type of the collaboration because of the collaboration becaus tumour or pulsation, but a slight thrill could be felt on The veins on right side of thorax were prominent and distended; there was no swelling of arm or neck, and total absence of pain. The radial pulse on right side was much weaker than on left, and occasionally the patient completely lost his voice. There was no difficulty in diagnosing aneurism of ascending arch, extending into right lung. The patient died suddenly after being three days in hospital. The specimen shows a sacculated aneurism, embracing the upper half of ascending arch, lying more posteriorly and laterally than anteriorly, behind superior vena cava. It extended in an upward and outward direction for about two inches, its width being about the same as its length. The sac seemed at its commencement to be made up of pericardium and pleura, but at its apex it was made up of semi-consolidated lung tissue. The whole length of the aorta was studded with atheromatous patches, varying in size from that of a sixpence to that of a two-shilling piece. Evidently the aneurism had its origin in one of those patches, and had suddenly burst into lung tissue. The two upper lobes of the right lung were consolidated.

ANEURISM OF DESCENDING ARCH OF THE AORTA PER-FORATING GESOPHAGUS.

Dr. W. J. THOMPSON.—The subject of this aneurism was also a builder's labourer, set. 47. The history given was that when going to lift some weight he suddenly collapsed, blood coming from his mouth. He had never complained of anything. At the post-mortem the stomach and intestines as far as the ileo-cæcal valve were found full of blood. Corresponding to the level of the seventh dorsal vertebræ there was a ragged opening in the œsophagus about the size of a sixpence, placed rather posteriorly, laterally, and to the left. This communicated with an aneurismal sac which sprung from the aorta anteriorly, laterally, and towards the right. The opening between the aorta and sac had a diameter of about three-quarters of an inch. The sac itself was small, had thin walls, which seemed to be made of the

outer covering of the aorta. There was only one small atheromatous patch situated in the transverse portion

Dr. Scott, Dr. Knott, Dr. E. J. McWeeney, and Dr. Lumsden discussed the causation of this condition, and Dr, Thompson briefly replied.

The Section then adjourned.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY, MERTING RELD WEDNESDAY, DECEMBER 21st, 1898.

SIE JOHN BATTY TUKE, President, in the Chair.

PROFESSOR CHIENE showed (1) a case of coxa vara in a lad of 16. It was apparently due to trauma received in childhood, and there was evidence of past rickets; (2) double congenital dislocation of the hip and symmetrical ununited fracture of both clavicles in a girl of 11-also ricketty.

Mr. CAIRD showed (1) a patient after removal of a rectal carcinoma by the para-sacral incision. In order to discover the exact relations of the growth laparotomy was previously performed. Now—three and a half months after operation—there was complete control of the rectum.

Dr. Melville Dunlop showed (1) a child suffering from diplegia with athetotic and choreiform movements The condition was not congenital, but had developed at the eighteenth month. There was a certain degree of imbecility; (2) a case of muscular dystrophy, combining the features of the atrophic scapulo-humeral and the pseudo-hypertrophic forms of the disease.

Dr. James showed (1) a case of scleroderma combined with Raynaud's disease; (2) a case of localised syphilitic

giantism; (3) angio-neurotic cedema of the tongue.

Dr. G. A. Gibson showed cases of bulbar and pseudobulbar paralysis.

Dr. Affleck showed (1) a brother and sister suffering from Friedreich's ataxia; and (2) a case of Addison's disease, which had improved very greatly under treat-ment with suprarenal extract. In a former case the extract caused such severe collapse that it had to be discontinued.

Dr. John Thomson showed a patient suffering from

hemiatrophy of the tongue.

Dr. George Elder showed (1) a case of hemiatrophy of the face, with malformation of the ear; and (2) a patient, æt. 60, suffering from chorea. The disease had lasted for five years, and now there was considerable mental impairment. Save in the absence of an hereditary tendency, the case resembled Huntingdon's chorea.

Dr. Allan Jamieson showed (1) a case of papulosquamous eczema, apparently syphilitic, affecting the palms; (2) a case of urticaria pigmentosa; (3) a case of psorospermosis follicularis vegetans (Darier's disease);
(4) the result of treatment in a case of tylosis; and (5) a case of elephantiasis.

Dr. Geaham Brown showed a case of Addison's dis-

Mr. Hodsdon showed a case of plexiform neuroma, associated with multiple subcutaneous neuromata.

The following specimens were exhibited:-

Mr. WALLACE: (1) Renal calculus; (2) kidneys with calculi in situ; (3) fibro-adenomata removed from prostate; (4) portions of prostate removed by suprapublic cystotomy; (5) four kidneys (three tuberculous, one carcinomatous) removed by operation; (6) dermoid cyst removed from floor of mouth; (7) biliary calculi removed by cholecystotomy; and (8) microscopic specimens of tumours and of prostate.

Dr. LOGAN TURNER: Skull showing unusual develop-

ment of frontal sinuses.

Dr. Dowden: (1) Plexiform neuroma, with microscopic specimens; and (2) specimens of hydatids.
Mr. CATHCART: (1) Abdominal aneurism; and (2)

multiple abscesses in brain.

Mr. CAIRD: Preparations and drawing from unsuccessful case of enterectomy and suture for carcinoma.

Dr. WILLIAM ELDER: Heart and intestine from a case of dysentery with ulcerative endocarditis; (2)

brain showing hæmorrhage into the occipital lobe; and (3) brain from a case of word blindness.

Mr. CAIRD exhibited a needle-case for sterilising needles and sutures.

Mr. CATHCART exhibited improvements on his micro-

Dr. Graham Brown demonstrated a new form of mathesiometer.

France.

FROM OUR OWN CORRESPONDENT.]

Paris, December 31st, 1898. ABLATION OF THE SPLEEN.

AT the meeting of the Société de Chirurgie, M. Le Dentu presented a patient who had been operated on for rupture of the spleen produced by the shock of the shaft of a car driven at great speed. The man was brought to the hospital in a fainting condition, and when examined rupture of the intestine was believed to be the result of the accident, and laparotomy advised accordingly. When the abdomen was opened it was found that it was the spleen that had been torn to the length of three inches. A large quantity of blood filled the cavity of the abdomen, but the ruptured vessels had ceased bleeding. It being found impossible to ligature, it was decided to remove the organ completely, and for that purpose a clamp was placed on the pedicle.

The patient made a very rapid recovery, and was at the time of speaking in perfect health.

INTERMITTENT HYDRONEPHBOSIS.

M. Bourcy spoke on the case of a woman, æt. 62, who for many years suffered periodically from severe pain over the left renal region, radiating towards the left groin, and accompanied by vomiting and a sudden cessation of the urine. After one or two days the pains disappeared, and the flow of urine returned with more or less abundance. Several times gravel was found in small quantities. The symptoms were evidently those of renal colic. However, three years ago matters took another turn; instead of subsiding in one or two days, the pain persisted, the urine remaining very scarce, while the abdomen increased in size, especially towards the left side, where an unbearable sensation of tension and fulness was felt and the vomiting as well as the headache continued. In this condition the patient applied to one of the hospitals, where she generally got relief by having the tumour tapped. A few days ago she came under the care of M. Bourcy, who, on learning the history of the case, had no difficulty in pronouncing it to be a case of intermittent hydronephrosis. At the time of entry she had already been suffering four days, the whole left side seemed to be the seat of a large fluctuating tumour, while the urinary secretion was reduced to almost suppression. By means of a Potain trocar the speaker drew off over a quart of liquid containing all the elements of urine. As in former operations relief was immediate, but M. Bourcy believed that if the symptoms returned in a short time ablation of the kidney should be practised.

ARTIFICIAL ANUS.

M. Lejars presented a girl, set. 13, who was born with an imperforation of the anus. M. Pean made an artificial anus two days afterwards. Several attempts were made by different surgeons to cure this artificial anus, but all failed. M. Lejars made an effort in his turn, but at first failed, however, having opened the abdomen, he found that the fistula of the artificial anus communicated with a large cavity reaching to the sigmoid flexure, having destroyed this, the fistula was easily closed.

ARTERIAL SCLEROSIS.

Two important and almost pathognomonic signs of hypertension of the arteries are, according to Professor Huchard, diastolic sonorous bruit heard at the base of the heart and on the right side of the sternum, that is to say. over the aorta, and the stability of the pulse regardless of position. In the normal state, the pulse diminishes by six to eight beats in the horizontal position of ordinary individuals, where sclerosis of the arteries is present the pulsation remains the same as in the vertical position-The treatment should take into account the cause and the effect of the hypertension. For the former he prescribes a rigorous diet composed chiefly of milk and other diuretics with a little white meal, and for the latter trinitrine as follows:-

Solution of trinitrine, 1º/o 40 drops; Water Яx.

A tablespoonful every 3 or 4 hours

Besides this treatment he orders baths, massage, dry frictions, &c.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 30th, 1898.

At the Medical Society Dr. Brasch brought forward the subject of

CHANGES IN THE GANGLIONIC CELLS IN FEVER.

At a former meeting he had shown nerve cells changed by high temperatures. They were from a preparation taken from a child who had died from scarlatina, in whom the temperature reached 41 C. Dr. Klemperer had suggested that the changes might be of a toxic nature and due to the heat alone. In order tomeet the objection the speaker showed further preparations for comparison (1) a human ganglionic cell from the anterior horn, (2, 3, and 4) sections of the spinal cords of children with pre-mortem high temperatures, one dying of gastro-enteritis, the second of pyemia, and the third of broncho-pneumonia, the pre-mortem temperature being respectively 39.5 41.5, and 42 C. The degrees of change as regarded the protoplasm, the Nissl's corpuscles, and the cell processes were interesting, inasmuch as they corresponded to the height of the temperature. Thus where the temperature was 39.5 the Nissl cell corpuscles were swollen, at 41.5 they were disappearing, and at 42 they had vanished.

The preparations were made from one to two hours after death, death being due to various causes, the only common feature being a high temperature. The changes closely resembled those taken from over-heated animals. For the production of these phenomena certain conditions were essential:-1, A certain height of temperature, at least 3 degs. C. above the normal; 2, the fever must be continuous; 3, it must be in association with some acute affection; in chronic diseases the cells seemed to accustom themselves to the raised temperature. For the rest the different cells were variously affected; the distribution also, in different individuals was not constant. With lengthened duration of high

temperature the changes were general and almost without exception.

Dr. Treitel had a paper on

THE NATURE AND SIGNIFICANCE OF CHRONIC TONSILLAR
ABSCESSES.

It was known that chronic suppuration in any part of the body constituted a danger to the whole system. Fraenkel first pointed out the danger of tonsillar abscesses. Later cases became known where articular rheumatism had commenced in the tonsils, and a similar relation was observed with regard to other diseases, cryptogenetic pyæmia, for instance. In simple angina, micro-organisms, such as streptococci, might enter the blood and set up disease in a locus minoris resistantiæ. The question now arose whether pathogenic germs could pass through the tonsils without setting up local inflammation. It appeared as if this were so; at least, the local inflammation was unnoticed, according to Fraenkel in a case where death occurred from streptococci, in which they were found in the tonsils, but without inflammation thereof. It was a question whether the intact mucous surface of the tonsils would allow them to pass, and in most cases this would be destroyed in places. Generally there was swelling of the gland, and later a tonsillar abscess which could be the starting period for general suppuration. These abscesses were usually so small as not to be distinguishable during life, as they did not lead to general swelling of the tonsils. The question would often arise as to whether these abscesses were primary or secondary In some cases, however, their primary nature was evident. The speaker then related the following case: A man, 63, had often formerly suffered from tonsillar abscesses, and more recently hoarseness and shortness of breath had come on. A few days before, difficulty of swallowing had presented itself. On examining the throat no symptoms of acute inflammation were observed. The laryngoscope showed cedema of the glottis, of the arytenoid cartilage, and of the aryepiglottic folds. The troubles got worse in spite of ice and other applications. Tracheotomy was performed. A foul abscess was then discovered around the cricoid cartilage, and the patient died. The autopsy revealed chronic tonsillar abscesses. As regarded treatment, this could only be prophylactic, as the small abscesses could not always be discovered. In case of recurrent inflammation he advised splitting the tonsils. and careful attention to the cleanliness of the mouth.

Dr. A. Fraenkel said that septicæmia was a tolerably frequent disease in his wards; that the source of infection was always sought for, and but rarely found, but when found was mostly in the tonsils. During life nothing could be found in the tonsils; the centre of disease was generally discovered only after death. A woman in the thirties was admitted into hospital with bad jaundice and pyæmic fever. Nothing abnormal was discovered at the heart beyond a short systolic murmur. The abdomen was swollen, the liver enlarged, but nothing abnormal in the fauces. He thought it might be a case of pyelophlebitis arising from perforation of the vermiform appendix. Death took place in forty-eight hours. The autopsy showed small abscesses in the tonsils and commencing ulcerative endocarditis. In another case a pericardial effusion could be traced back to a primary tonsillar abscess. An interesting observation had been made that day. In a case of sepsis that had been diagnosed during life by examination of the blood, there was a

large splenic tumour and continuous fever. The incubation blood showed sepsis, streptococci in such numbers that speedy death might be expected. The autopsy showed that the point of entrance was the genital tract, following abortion.

Dr. Benda objected that Treitel had grouped two things together that pathologically should be kept separate:—1. A group of infections, the point of entrance of which was often difficult to discover, as generally only a few micro-organisms were formed at first, but which afterwards multiplied in the circulation. 2. Actual pyæmia, when a spot was always found where a thrombosis had taken place, in which the germ had developed. Fraenkel's case was one of valvular inflammation, set up by streptococci, when as a rule the exit point of these streptococci was difficult to determine, in that case streptococcus thrombi were found in the small veins of the valves.

SOMATOSE AGAIN.

Dr. Fried. Köebl, "D. M. Z.," No. 86, considers somatose to be the best nutrient material we possess, in consequence of its high percentage of albumen. In anæmia, chlorosis. in milder cases of tuberculosis of the lungs, in debilitated neurasthenics, in convalescents after exhausting illnesses, after operations, and in women in childbed it is of the utmost possible service. In the majority of cases increase in weight and in the number of red blood, corpuscles was brought about. In infants a more favourable relation of the casein to the albumen was procured by the addition of somatose to cow's milk. When coagulation takes place the gastric juice acts more readily after somatose is added, and by this means its value as a food is increased. The somatose preparations (Bayer Elberfeld) of cocoa, chocolate, kola, Malaga wine, &c., have proved agreeable and strengthening, both for the healthy and the unhealthy.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 30th, 1896. A WOULD-BE SUICIDE.

SCHNITZLER produced another man who had been brought into hospital immediately after attempting suicide by means of a knife, which he had inserted at the left mammilla. On examination, the area of cardiac dulness was tympanitic, and when the body was shaken a metallic splash was to be heard. After an hour had elapsed the temperature rose, this was accompanied with severe pain in the left side of the abdomen—not the thorax -which according to French authors would indicate a wounding of the intestine. With such a hypothesis in view the wound in the chest wall was freely opened to explore its extent and direction, which had evidently escaped the heart and passed through the diaphragm, but no injury was done to the bowel or abdominal contents. After a slight reaction the wound healed and the patient perfectly recovered.

LABORATORY AND PEST.

A little consolation is taken by the Viennese as a sedative for the late excitement that Vienna is not the only place where the laboratory is a source of danger. It seems that Yersin infected the town of Nha-Tsang (Indo-China) in a similar manner, where he had been injecting mice with the pest serum. From these mice the infec-

tion reached man, but was not so easily checked as it has been in Vienna.

At the Vienna Medical Club, Nov. 16th, 1898, Dr. R. Kienböck gave a further account of the results obtained by

RONTGEN EXAMINATION OF CASES OF PYOPNEUMO-THORAX.

The first paper on this subject, read at the Vienna Medical Club on April 20th, 1898, is published in the MEDICAL PRESS AND CIRCULAB, p. 517, May 18th, 1898.

He has examined a certain number of young people of the male sex suffering from tuberculous pyopneumothorax-both on the left and on the right sides-with large empyemata, showing the signs of free movement. In every case there were to be seen on the Rontgen screen movements of the exudations, even when the patient remained quite still, viz., respiratory and pulsatory phenomena—exactly as described in the first article with the experience of a single case (1) inspiratory ascent and expiratory descent of the fluid level, (2) waves on the upper margin of the fluid carried by each contraction of the heart This pulsation of the empyema was less marked in the case of pyopneumothorax of the right than of the left side as might be expected. There was no concussion of the thoracic wall either on inspection or on palpation. The paradoxical respiratory movement of the surface level is to be explained on the assumption that this half of the diaphragm was paralysed, and therefore the inspiratory descent of the sound half raises the other one, carrying with it the fluid, by the intermediary of the contents of the abdomen. He calls this phenomenon the "alternating respiratory movement of the two halves of the diaphragm." The author lays stress upon the fact that both phenomena appear to be pathognomonic in cases of the kind just described.

Dr. R. Kienbock, at the Vienna Medical Club 19, x. 1898, exhibited a Rontgen demonstration of a young man (from the Medical Klinik of Professor v. Schroetter)

REVOLVER-SHOT LESION IN THE REGION OF THE HEART. He had tried to commit suicide the previous day by means of a revolver of 7 mm. calibre, aimed at the wall of the thorax three fingers breadth below the left nipple. The situation of the ball could only be detected by skiascopy. It had been reflected under the skin from the sixth rib in the left mammillary line and had proceeded to a depth of two centimetres. It was situated either in the substance of the diaphragm-viz., in the anterior descending part which helps to form the anterior pleural sinus or else in the lung which fills the latter depression. In any case it was situated in the middle line below the apex of the heart and in close proximity thereto. (The ball could easily be seen on the screen against the light, air-filled stomach which forms the background.) It was remarkable that the ball showed two sorts of movements, respiratory and pulsatory; for it followed both the movements of the diaphragm and of the apex of the heart moving in directions corresponding thereto. important injury appear to have been caused by the ball.

The Operating Theatres.

GUY'S HOSPITAL.

DEEP SARCOMA OF THE NECK .- Mr. ABBUTHNOT LANE

nearly a year from a lump which appeared at first immediately above the right clavicle, and gradually extended upwards into the neck as it increased in size. It had not led him to obtain medical treatment till recently owing to the fact that it caused him no inconvenience. Lately, however, he had complained of pain in the arm, sometimes in the shoulder and at other times in the entire arm. He had lost flesh within the last month. The lump, which was as large as an orange, was situated beneath the sterno mastoid, it could not be moved about, on the subjacent structures. The traches and osophagus were displaced by its pressure. There seemed little doubt that the mass was a sarcoma which arose in the spinal column. It was freely exposed; the brachial plexus then was seen to enter it and probably traverse it; it was quite impossible to remove it in its entirety owing to its deep attachments; consequently Mr. Lane incised it, and was able to shell out the soft, cheesy-like growth from the interior of the ramifying spaces, and from about the nerves which passed through it. It was then possible to remove much of the capsule. The cavity was plugged with sulphur and gauze in order that any residual growth might be destroyed. Mr. Lane feared that it was hopeless to expect other than considerable temporary alleviation from this procedure, though it offered the patient a chance of complete recovery.

HOSPITAL FOR SICK CHILDREN.

Intussusception.-Mr. Arbuthnot Lane operated on a child who had been suffering from intussusception for a little more than twenty-four hours. A large elongated mass was felt, placed vertically to the left of the middle line and extending downwards almost to the anus. On opening the abdomen the intussusception was reduced with sufficient difficulty to convince the operator that most probably reduction could not have been effected by inflation. This applied rather to the evolution of the last two inches of bowel, which were very thick, and required considerable direct firm pressure between the thumb and fingers to restore the thin concave aspect of the cæcum to its normal convex form. A careful examination of the part showed that the intussusception had started as a dimpling inwards of the outer aspect of the cæcum on a line with the ileo-cæcal valve, and it was the convexity found by this intrusion into the bowel that formed the summit of the intrusion. Mr. Lane believed that this was the manner in which intussusceptions usually arose. He had seen as many as four intussusceptions in the same case arising from the intrusion of Meckel's diverticulum into the ileum, where it formed the summit of the highest of the four intussusceptions, which was compound in character. At first the large round cherry-like mass in the bowel, formed by the inverted and swollen diverticulum, suggested the presence of an adenomatous polyp, such as he had met in a somewhat similar condition.

Mr. Lane pointed out that as the operation was done at a comparatively early date in the history of the accident the manipulative procedures were effected with ease, and with little shock to the patient.

ST. THOMAS'S HOSPITAL.

Unusual Case of Hernia of the Appendix .- Mr. BATTLE operated on a woman, æt. 60, for a swelling in the right groin. The history she gave was that five years ago she had pain in the groin, and that a lump formed operated on a man, æt. 34, who had been suffering for there. She was afterwards in bed at home for a fort-

night, and then in a London hospital for a month swelling gradually disappeared and caused no further trouble. Ten days before the present operation a somewhat similar swelling had appeared in the same situation, and had caused a good deal of pain and discomfort; there had been no vomiting, and all her symptoms were referred to the groin. On examination there was a prominent, somewhat irregular swelling in the right femoral region. It was tender, firm, gave no sense of fluctuation, and was without impulse on coughing. Its size could not be reduced on pressure, nor could it be moved from the deeper parts. It appeared, however, to have a neck which passed to the femoral ring. The diagnosis lay between hernia, inflamed glands, and a combination of the two. The surface of the tumour suggested inflammatory enlargement of the glands, as did also the tender-In favour of ness and fixation of the parts. hernia as a somewhat unusual history of the previous attack, together with the rapid onset of the present attack, and the fact that there appeared to be a neck to the swelling in the situation of the femoral ring. Against hernia was the complete absence of tumour between the two attacks and the absence of impulse on coughing at the present time. A sign which Mr. Battle has sometimes found of use in doubtful cases was however present. When a hernia is irreducible pressure in the iliac fossa from below upwards will frequently cause a sensation of dragging in the tumour, and this the patient experienced in the present case. Exploration was advised and readily agreed to. After incision of the superficial structures the lump was found to consist of an inflammatory mass to which adhered several inflamed glands. No hernial sac could be found by direct incision, so the mass was turned outwards and peritoneum lining a hernial sac was discovered. Inside this, was a fatty process like one of the appendices epiploicæ about the thickness of the little finger which ran to the bottom of the sac where it became lost in the inflammatory mass; it could not be drawn down any further, and on examination a rounded portion of bowel was found accompanying it: this was the appendix vermiformis inflamed and adherent to the inflammatory mass The fatty process before mentioned. WAR mesentery of the appendix, and its division necessitated the application of one or two ligatures to bleeding points. The appendix was removed by the coat-sleeve method, and the hernia returned into the abdomen. The neck of the sac was quite small, the sac itself so adherent to the surrounding parts that it could not be dissected up. The greater portion of it was cut away with the inflammatory mass and adherent glands and the opening of the sac closed with silk sutures. Sutures were also passed between the fascia over the Pectineus and Poupart's ligament. The case, Mr. Battle said, was a specially interesting one, the exact diagnosis being difficult, if not impossible. Further, he pointed out, hernia of the appendix alone is a very rare occurrence, and it is still more rare for the appendix to become inflamed when outside the abdomen. Such an appendicitis is less dangerous than when it takes place in the iliac fossa, but this happy arrangement cannot always, unfortunately, come to pass. The appendix showed a condition of catarrhal inflammation, its apex being cicatricial in character and incorporated with the surrounding inflammatory mass.

" SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 4, 1899.

THE GENERAL MEDICAL COUNCIL: AN IMPEACHMENT.

In endeavouring to realise the present position of affairs we must first ask what are the duties of the General Medical Council. According to their own definition the chief functions imposed upon them are the regulation of medical education, and the maintenance of the purity of the Register. These self-defined duties have admittedly been fairly well discharged in the matter of education. although it may be doubted whether scheme can be altogether satisfactory unless. based upon a one-portal system. As to maintaining the purity of the Register, the Council's administration may be described as a depressing failure. It seems tolerably certain that statutory powers exist whereby registration may be made indispensable. At present the Council keep a tight and often needlessly irritating control over registered medical men, while those that are qualified, but unregistered, are allowed to work any evil they like with impunity, so far as the Council are concerned. As to the safeguards for protecting the Register from fraud, they are non-existent. As pointed out in the MEDICAL. Press and Circular ten or a dozen years ago, there is no organisation whatever to preventpersonation as regards either the obtaining or the holding and registering of qualifications to practise. A week ago the possibility was demonstrated to the hilt in a London police-court, where one Rowland was charged with personating a licentiate of the Irish Colleges of Physicians and Surgeons, who left England in 1895. In the course of the proceedings Dr. A. G.

Bateman, the well-known Secretary of the Medical Defence Union, swore that in the summer of 1895 he communicated with Rowland, and then advised the Council not to register any person under the name of E. G. Nugent. But in their wisdom the General Medical Council admitted Nugent to that Register which it is their pride and their chief function, according to their own showing, to maintain in a state of spotless purity. At their next meeting it is to be hoped that the full history of this transaction will be made public, and that the necessary papers will be produced to show what steps, if any, were taken to test the evidence of qualification produced by the so-called E. G. Nugent after the receipt of the warning by a responsible body like the Medical Defence Union. Unless a clear explanation be forthcoming the scandal should be enough to break the back of any public body that has a healthy regard for its reputation among the community. In another direction an attempt has been made to maintain a high ethical standard among the registered practitioners by charging a licentiate of the Society of Apothecaries, the late Mr. H. K. Hunter, with falsely assuming the title of physician. Unfortunately, Mr. Hunter died soon after that prosecution, which we have since learned was authorised by members of the Council on the representation by the Penal Cases Committee that the accused was an unqualified practitioner. Again we say, that if the facts be as represented they point to a reckless want of organisation and of recognition of responsibility. But the sins of omission on the part of the Council are in the minds of the bulk of the profession not less weighty than those of commission. Council, for instance, make no serious attempt to defend the interests of those on the Register by resisting the inroads of unqualified practice. That important subject, however, cannot be discussed here further than by stating that there is a strong probability, amounting, in point of fact, to little short of certainty, that the Council possess ample powers for the suppression of unqualified practitioners. We believe, on that and other grounds, that we simply re-echo the wishes of the vast majority of medical men in demanding an exhaustive inquiry into the constitution and work of the Council, with a due sense of responsibility and with a full recognition of the difficult, and often delicate, nature of the duties devolving upon such a body. We nevertheless venture to submit that the Council have failed to grasp the issues at stake, that they have endeavoured to evade all efforts at healthy and desirable reforms, that their methods are cumbrous, costly, obsolete, inefficient, secret, and cratic, and at times unjust, and that the hour has come when in the interests of the profession the General Medical Council should be superseded by a body more in touch with the times and with the representative principle that underlies all sound administrative government. If the Council cannot forthwith be born again, then let it perish. A Government inquiry may perhap

bedesirable, but reform of some sweeping kind must be insisted upon if medicine is to gain the position of a self-respecting and properly governed profession. A consolidating and amended Medical Act is urgently needed, but meantime much can be done, as Mr. Horsley has repeatedly shown, by putting existing legal machinery into action. Things have gone so far, and the patience of a long-suffering profession has been so sorely tried, that the only alternatives left to the Council are either straightway to amend their ways or to look to their weapons.

THE FUTURE MASTERS OF THE PRO-FESSION IN IRELAND.

Some months ago we were handsomely abused by one of the introductory lecturers in Dublin, because we had expressed our grave apprehensions that under the new Local Government scheme, the last state of Irish Poor-law medical affairs might be worse than the first. We were roundly told that we should put our trust in Providence and welcome the chosen of the new elector as, at least, the makings of a capable administrator and an honest man. Remembering what long experience has taught us of the qualities of the elected committeeman and guardian, and seeing no reason whatever to suppose that the leopard would change his spots because his official name happened to be changed by Act of Parliament, we felt unable to participate in the sanguine hopes of the lecturer or of the newspapers which echoed him.

The recent prosecution of not one but many of the Kilrush Guardians for wholesale and persistent bribery and corruption in the election of successive officers of the Union in which they were voters is an object lesson which cannot be ignored. The evidence has proved that, without a shadow of doubt, not one but more than a dozen of these chosen administrators of the public trust of the Union, not on one occasion only but regularly, as a matter of business whenever an election came off, sold their votes as openly as votes were ever sold in the old corrupt elections; they higgled for their price, and were assisted in their market by officials of the Union and others. This system extended over a series of years, and covered the election of medical as well as other officials, and the culmination of the rascality was when the mother of one of the candidates appeared in public to demand the restitution of £460 which she had paid in bribes at the rate of £40 or £50 per head to the guardians for the election of her son. These persons, together their agents, have been sent to gaol for varying periods, and for the present the Kilrush scandal is at rest. Nevertheless, we want to ask two questions. Where were the inspectors of the Local Government Board all the time this was going on? Is it to be believed that they went their rounds to the Kilrush Union without hearing a whisper of this corruption? If so, in our opinion, they were totally unfit for their inspectorial position. Is it to be supposed that the Local Government Board knew all about it, yet kept its tongue in its cheek and refused to move?

We shall, no doubt, be answered by the asserthat Kilrush is an isolated case, and that all Ireland's guardians outside that district are as pure as the driven snow, to which we reply that, from information which we possess, we hold the opinion that the elected guardian and committeeman is just as ready to accept, and does accept, bribes in other districts as in Kilrush. We have been told lately by a candidate for a medical officership that when he went down full of hope to canvass the electors for an appointment a friend took him aside and presented him with a list of fifteen names of guardians with the price opposite each, at which he could be bought with a certainty. If these things are done in the green tree what may be done in the dry?"

THE CONSUMPTION CRUSADE.

SINCE the immortal Jenner elaborated the system of prophylaxis against small-pox which a pusillanimous Government has recently abandoned in deference to the political influence of a crowd of noisy ignoramuses, no such far reaching and, may we say glorious a movement has been started as the National Crusade for the extinction of tuberculosis, which was inaugurated, under the aura of sovereignty, at Marlborough House a few days since, and to which we have already briefly alluded. Heretofore, the terrible extent of tuberculous disease was fully realised by the profession but, until Koch isolated the specific bacillus, scientists were simply groping in the dark. It was before that time universally accepted that tuberculosis was a disease of heredity—that it was futile to attempt to prevent or anticipate it, and that the last hope of preventing its progress was to protect the inflamed lung by confining the patient to warm rooms or warm climates. We now know, Heaven be thanked! that all this is nonsense, that heredity has nothing to say to it except that it may produce a constitution in a patient which is peculiarly prone to any form of contagion. We know that climatic conditions, save to this extent, have little or no influence, and, to be brief, that the one and only thing which can produce consumption is the ingestion by the victim of the tuberculous microbe. Happily this consideration brings the prevention of consumption (to a very great extent) within the reach of sanitary law. Imprimis, it is quite possible to prohibit the sale of tuberculous meat and milk, which have been shown to be among the most potent disseminators of consumption. The process may be troublesome, expensive, and as unpopular with butchers and cowkeepers as the suppression of pleuro-pneumonia was but it can be done and, without doubt, it will be done as soon as the new Crusade brings it home to the comprehension of the nation that thousands of lives and untold thousands of pounds annually depend upon it. The third essential of prevention is much more difficult to attain-i.e., to prevent the dissemination of the disease by the expectoration of phthisical patients, but, even in this direction, vast should not regard such an expenditure as by any

good may be achieved by the education of the public, which is the principal purpose of this Crusade Patients may be drilled into the conviction that, in their own homes, and, when they can, elsewhere, they should carefully disinfect their expectorations, but it is hard to expect the multitude of working people to call attention to their own infirmity by carrying a spit-cup with them to their work and elsewhere. As for the ultra-sanitarian suggestion that, should they fail to do so, they should be collared by a policeman and conveyed to jail, we may, at least for the next quarter of a century, put it aside.

The last of the proposals submitted to the Prince's meeting and adopted as part of the work of the new Crusade, is the establishment of sanatoria for consumptives in favourable sites in the United Kingdom, and we regret that, however we may approve of such a project, we cannot look upon it as a potent means of exterminating tuberculosis from our community. That such sanatoria conduce to the recovery of phthisicals and do. in fact, produce a gratifying proportion of actual cures may be taken as proved, and, this being so, the multiplication of such institutions would be an unalloyed benefit for which reason, the capitalist who contributes his money, as Messrs. Beit and Wherner have done for this object, may be assured that he has spent it for the best advantage of the public. Moreover, very much may be done by the establishment of sanatoria for upper and middle-class people who can afford to pay a minimum maintenance contribution, and by these means, perhaps subsidised to some extent by public funds, a large section of the phthisical centres of contagion may be eliminated from our midst, but when we learn from Sir William Broadbent that 70,000 persons die annually in England and Wales alone from tuberculosis, we cannot but recognise that sanatoria, however well organised, can do little for our overwhelming phthisical population. The example of one such sanitorium which we believe to be, in every sense, well and economically worked will serve to illustrate our meaning. Phthisis is a disease the treatment of which is necessarily very prolonged, and the "turn over" (so to speak) of the bed accommodation of such institutions is extremely small. The sanatorium of which we speak has twenty-four beds, and its maintenance income (irrespective of building and all other extraordinary charges) tots up to £56 per bed. Each bed "turned over" a patient, on an average, in 109 days, so that each patient, including those who did not require to be detained in hospital, cost the institution over £14. Supposing that the number of actual deaths from consumption throughout the Kingdom in a year as stated by Sir William Broadbent (70,000) only represent half the number of those requiring sanatorial treatment, we have an army of 120,000 to be accommodated, who, at the rate of £14 a head, would cost somebody £1,680,000 a year, not to mentian the enormous initial outlay for providing the requisite buildings and accommodation. We

means too high a price to pay for the extinction of tuberculosis, even if the payment extended over a score of years, but until public opinion is thoroughly aroused, we apprehend that the taxpayer will regard this method of dealing with consumption as altogether Utopian. Whether there may be other less expensive methods of dealing with the tuberculous population remains open for discussion.

Aotes on Current Topics.

The Awards of the Prince of Wales's Hospital Fund.

THE list of awards of the Prince of Wales's Hospital Fund was published on Saturday last, and the London Hospital Charities now know the worst or the best, respecting the financial assistance which they will derive therefrom. With the approval of the Prince the operations of the Fund have this year been limited to hospitals lying within a radius of seven miles from Charing Cross, an arrangement which we believe to be satisfactory for several reasons. We learn also that of the hospitals which applied for grants, and whose claims were considered, all but twelve were included in the list of awards. The explanation youchsafed for withholding the awards in the twelve instances is that some of the institutions were deemed to be adequately provided for by the Hospital Saturday and Sunday Funds, while a few more, by reason of their management - presumably mismanagement - were ruled to be undeserving of support. next to the list of the hospitals benefiting by the Fund, we find that twelve institutions are classified as requiring an annual grant, of which nine are general hospitals and three are special, the latter being the Seamen's-always the Seamen's now - the Hospital for Sick Children, Great Ormond Street, and the National Hospital for the Paralysed. It is not difficult to understand, having regard to the composition of the Committee of Distribution, how it is that these three charities should have been included in the annual list. But what does the annual list mean? Are we to understand that in the future the hospitals named toerein will be paid large grants before the claims of any other institutions will be considered? Further, are we to conclude that the list is final, and that, in succeeding years should the fund continue, no other additions will be made to it? These are questions to which answers should be forthcoming in the interests of the hospitals generally, and in the Fund in particular. Of the general hospitals mentioned two, the London and Guy s, receive an award of £5,000 each. This amount we believe to be a mistake. Practically speaking a third of the whole fund is thus awarded to two institutions, an arrangement which is not only unjust but inexpedient. We think that no award should exceed, say, two thousand five hundred pounds. Clearly the object of the Fund should be to do the greatest good to the greatest number of the charities concerned, but such an object is

obviously an impossibility when two or three especially favoured institutions are allowed to absorb the bulk of the proceeds. The next detail to which attention may be directed is with respect to the conditions attached to the grants awarded to certain other hospitals, and the first which claims notice in this regard is the award of £500 to the West London Hospital. A grim satire is contained in the condition that the overcrowding in the insti-The committee of tution must be abolished. inspection who visited this hospital found that the wards were undoubtedly overcrowded, but they also found that a new wing, containing seventy-five beds. was ready to be opened as soon as funds permitted. Instead, however, of enabling the hospital authorities to obviate overcrowding by opening the new wing, the distribution committee merely award a sum of £500. with an intimation that the overcrowding must cease. In curious contrast, however, with the above is the award of £750 to the Great Northern Central Hospital, on condition that fifteen beds be reopened.

THE MEDICAL PRESS.

Quackery Rampant in Houghton-le-Spring.

THE recent failure of the prosecution of the "botanist" Steel drives home the lamentable failure of Clause XL. of the Medical Act to convince the average bench of magistrates. This notorious quack has carried on a flourishing practice in spite of a former conviction, and is at present the proprietor of a club with upwards of four hundred members. Unfortunately, when the magistrates decide a case of this kind upon a question of fact there is no further chance of appeal. Certainly if the General Medical Council had possessed any decent amount of energy or interest in the law which they were created in order to administer they would long ago have secured final decisions in the High Courts upon all debateable readings of the Medical Acts. Then, where the wording of the clauses was at fault, or the intention of the legislature vague, they would have taken stepsto get the law amended and strengthened. As it is all is chaos, and the medical profession is the happy hunting ground for all kinds of interloping marauders, and here, at the end of the nineteenth century, the law is powerless to stop such a shameless quack as Steel from flaunting his illegal medical practice in the face of the community. This fellow actually has the impudence to print his own death certificate forms, and the branch Registrar of the district admitted he received them. Why is this allowed? Such a proceeding looks like a direct sanction of quack practice by Government. At least let an inquest follow every death that takes place under an unqualified man. Why should not the signing of death certificates by an unregistered person be made a penal offence?

THE manufacture of Fellows (save the mark) of the Spectacle Makers Society, goes on swimmingly. It is announced that there are now two hundred craftsmen as members of the Guild, besides thirty liverymen.

Hospital Abuse in Bradford.

OUR attention has been drawn to a long letter from a medical man addressed to the Bradford Observer, and pointing out a number of hospital abuses in that town. The name of the writer is a sufficient guarantee for the accuracy of the facts, and as it stands this communication forms a damning indictment of the way in which charitable funds are squandered in the relief of well-to-do persons. The pith of his matter lies in its sharp specific instances. wherein he forms a notable exception from the usually diffuse and general nature of such criticisms. The following instances may be selected:-"Will your readers be surprised," he asks, "to hear of a gentleman residing in an expensive house in a select locality in the West End of Bradford being attended for charity? Of course he would not condescend to go for it, to be jostled by the crowd waiting in the infirmary, so the infirmary sent one of its staff to the house to dispense medical charity. In another case, a man suffering from dyspepsia, the result of his drinking habits, was attended gratuitously at the same institution, while he lived comfortably on the income derived from his property. Another patient was a consumptive girl, whose father "was a commercial traveller in a good situation, with whom resided two unmarried adult children, both earning good wages, while a third unmarried child earned £400 a year in another town." Again, the infirmary relieved a boy, the son and grandson of well-to-do persons, who could afford to pay £13 to that institution and six guineas to a consultant, in addition to their ordinary medical attendant. In another case, a woman on a pleasure trip from America received many weeks free treatment for her son, who suffered from "spots" on the back of his hand. All this and very much more to the point is concisely stated by the writer, who pertinently asks how these abuses have escaped the notice of the "keen business men on the board," who, according to the public statement of the chairman, inquired into and dealt with every case brought to the infirmary. Clearly there is a good field for the labours of such a body as the Hospital Reform Association in this same keen business locality of Bradford. What are the medical men of the town thinking about to allow these abuses? It is more than likely that a united and vigorous protest on their part would bring about a desirable reform in this most unfair form of subsidised competition.

The Indian and Colonial Pharmacopœia.

A PRAISEWORTHY desire is expressed by the General Medical Council to produce "sooner or later" a Pharmacopœia which will be equally useful in every part of the British Empire. The Council also desires to recognise special articles for special colonies or dependencies in such a manner as to avoid undesirable substitution of one drug for another distant parts of the Empire. The report of the Pharmacopœia Committee appointed with this object has alres by been received and adopted by the General Medical Council, and will shortly be issued.

We have been favoured with an advance copy of this Addendum. The first drug on the list is Agropyrum. old familiar friend, couch grass, Triticum repens of the United States Pharmacopæia, which has long been used as a demulcen diuretic and sedative. It is frequently prescribe in cases of chronic cystitis, irritable prostate and gleet. Datura leaves are suggested by the Indian Government Committee as an equivalent in India for Belladonna leaves, and by the Hong Kong authorities for use in addition to Stramonium leaves. Datura seeds, the seeds of Datura fastuosa will also be recognised as a substitute for stramonium seeds. Exacum will be made official in India in place of Chiretta. One of the most notable additions is that of Cotton root bark. Gossypii Radicis Cortex which has active emmenagogue and oxytoxic properties. Some years ago, if we mistake not, in a trial for criminal abortion it was shown that the prisoner was in the habit of prescribing this drug, and it was stated by the medical experts engaged in the case that this remedy had no known legitimate use. It would appear that the pharmacological knowledge of the accused was somewhat in advance of that possessed by those who condemned him. It is indeed to be feared that in only too many cases the so called expert is a person who knows less about his subject than the majority of his professional brethren. Jasmine, which in India has a reputation as a lactifuge, is another new introduction which may prove useful, while Ajowan oil, which cont ins thymol and cymol, will in India take the place of peppermint, caraway, and other drugs containing essential oils. Oil of lemon grass, the Indian oil of verbena, is new, and will be found useful in cases of chronic dyspepsia attended with flatulence. Grindelia robusta is recommended provisionally, and we are told that "the books" allude to it as a remedy in bronchitis, asthma, and whooping-cough. As a matter of fact it has been extensively used both in England and in the United States for the last twenty years. The Pharmacopœia Committee seems to be a little bit behind the times, but we have no doubt that the Addendum when published will prove useful.

Taste Depravity of Inebrates.

THE use as a beverage of "finish," a weak solution of shellac in spirit employed by French polishers, is an old story, but we believe that its use for that purpose has fallen into abeyance in consequence of new regulations made by the In'and Revenue to prevent its sale for the purpose of drinking. Similarly the drinking of methylated spirit, a horribly nauseous concoction, increased, nevertheless, until it became necessary to add a stronger dose of methyl. A still more inconceivably repulsive form of tipple was the spirit drawn off museum preparations, and yet we believe that the drinking of that beverage has been the death of many museum porters, and it is a long-time reminiscence that the Royal College of Surgeons, Ireland, on the appointment of a new Museum Curator, discovered that several hundreds of pounds worth of its specimens had been destroyed by the abstraction of the spirit from the bottles, the past

curator having been a confirmed inebriate. latest advance in the direction of a new intoxicant is the drinking of petroleum oil a practice which is stated to be rapidly growing to the dimensions of a great national vice in France. The taste of the liquid is absolutely repulsive, but to the Britisher who has tasted the abominations which are drunk with avidity and craved for by the French working classes, it will be obvious that nauseousness is not, of itself, a bar to the use of any beverage once that the taste has been broken in to tolerate the liquid. The worst of the new intoxicant, from a social point of view, is that petroleum, taken in any reasonably quantity does not appear to be greatly detrimental to health. It is said that the drunkenness which it produces is of the morose and quarrelsome type, and not of the jolly character which arises from alcohol, but the fit is quickly slept off, and the victim awakes apparently not much the worse for his "outing".

The Marriage of Ovariotomised Patients

MANY years ago, in commenting on some statistics then before us concerning the subsequent history of patients who had had both ovaries removed, some of whom had married "and been happy ever after." we ventured to suggest that marriage under these circumstances was of the nature of a fraud unless the bridegroom had been duly informed of the mutilated condition of the otherwise eligible woman of his choice. We suggested, moreover, that the absence of the organs essential to reproduction which. according to the Church Service, is the aim and object of the institution of marriage, would not improbably be considered by the Courts to constitute a ground for declaring such marriages null and void. This point has recently been judicially considered by the American Courts with a somewhat curious result. The Supreme Court of New York apparently dissents from the view that inability to procreate, artificially induced, infers a disability "to enter the married state." This strange view is based on the physiological fact that women who have passed the menopause are equally incapable of procreation, and it has never been urged that such marriages are, or ought to be, stricken with nullity. It is argued that there is no essential difference between a woman who through no fault of her own, has lost her ovaries through a surgical operation, and one whose ovaries have become functionally inactive through the operation of natural causes, and if one be held incapable of marrying there is no process of reasoning by which the other can be considered capable. The Court, therefore, expresses the opinion that the possession of the organs necessary to conception cannot, as a matter of law, be held to be essential to entrance to the married state so long as there is no impediment to the indulgence of the passions incidental to that state. Unfortunately, this judgment is beside the mark, for it leaves on one side the crucial question whether, if a man marries in ignorance of his wife's mutilation, he is not entitled to relief. We know of no authorised view of marriage other than that it is an institution for the procrea-

tion of children, and for the vast majority of persons this is, we presume, the ultimate object of the self-imposed sacrifice of sexual liberty. these circumstances we feel confident that the Courts in this country would take a somewhat different view of the responsibilities which marriage entails and infers, and would hold that the aggrieved husband had not received the "nature, quality and substance" which he contracted for.

The Insurance Offices and Vaccination.

THE practice of taking out life insurances has of late vears become more and more popular, so much so, that the offices concerned therein have added greatly to their business and incomes. The increase in the number of insurances, however, has manifested itself mainly in connection with children. Among the lower classes especially, the practice of insuring children's lives has spread to an extraordinary and, from one point of view, disquieting extent. In view of all these facts the question arises-How will the insurance companies regard the action of the conscientious objector in refusing the protection of vaccination to his children? This matter is attracting some notice in the insurance offices, and a rumour is current that the companies are contemplating the refusal in the future of policies upon the lives of unvaccinated persons. An unvaccinated person is regarded as a "bad life," and as such too risky to accept. If this plan of action were agreed upon by all the large insurance offices, no doubt the effect would be for a time to check the wilv designs of the conscientious objector. But human nature is such, and the competition for business so great between the offices, that we have not much faith in the policy being successfully carried out. We should imagine that even if all the existing offices were to refuse unvaccinated persons a new concern would at once be floated ready to take at the usual rates every person in the kingdom who had neglected to be vaccinated.

Contra-Indications to Breast Feeding.

THE indications for bringing up an infant at the breast are too numerous and too manifest for it to be necessary to dwell upon them, but it must not be forgotten that there are conditions in which this plan is contra-indicated. Tuberculosis, for instance, ought to be regarded as disqualifying the mother for the post of nurse. The objections that apply to the use of the milk of a tuberculous cow apply equally to that of a tuberculous mother, at any rate when the disease has passed the initial period. An anæmic mother is not likely to furnish a recommendable supply of milk for her offspring, who is very probably already suffering from physiological impoverishment as the consequence of a debilitated pregnancy. The various cachexize again formally contra-indicate suckling as well for the sake of the mother as of the child. Epilepsy and chorea are what may be termed mechanical contra-indications, in that they expose the child to the risk of injury. It seems hardly necessary to add that hereditary syphilis is a contraindication, but we doubt whether it is regarded as such by the majority of practitioners at the present time. Local contra-indications consist in deformations of the nipples or lesions which render suckling painful or impossible. Lastly, it must be borne in mind that the milk of a mother who is taking certain drugs may become poisoned. Iodide and bromide of potassium, for instance, have been known to set up the characteristic skin lesions in the infant in a severe form, although the mother may have been quite free from any symptom of the kind. The infant, being much more sensitive than the mother, suffers in a disproportionate degree from the effects of such drugs.

Post-Mortem Examinations.

MR. BRAXTON HICKS, the coroner who was so un. graciously handled the other day by Mr. Plowden the metropolitan magistrate, on the hearing of the charge of perjury against a surgeon, has, we are pleased to see, received the support of Mr. Thomas Bond, the well-known medico-legal expert. This gentleman, in a letter to the Times, commends the coroner's conduct in this case, and adds some very pertinent remarks and anecdotes concerning the more than perfunctory way in which post-mortem examinations are sometimes carried out. Mr. Bond amply confirms the protest which we have often felt it our duty to make against the practice of entrusting these exceedingly important duties to the nearest practitioner, without regard to his competence in the matter. Unfortunately, it is not only ignorance which we have to fear at the hands of these amateur medico-legists, but, possibly even more frequently, gross negligence and carelessness, of which Mr. Bond gave several salient instances. We fully concur in his opinion that the gross injustice to which Mr Braxton Hicks was subjected should be officially brought to the notice of the Home Secretary, and the proper person to do this would seem to be Mr. Hicks himself.

White v. Brown Bread.

A REACTION has set in in certain quarters against the use of brown bread, on the ground that it is much less nutritious than white. This may be the case, and, it may perhaps be conceded, moreover, that white bread is theoretically, at any rate, much more digestible than brown; but the reformers seem to overlook the fact that brown and whole-meal breads are not selected on account of any fancied superiority in these respects over white bread. On the contrary, it is precisely because there is a larger undigested residue to stimulate the intestines to action that these brown breads owe popularity. Constipation is one of the commonest and, in a minor degree, one of the most distressing ailments incidental to civilised life, and is responsible for a good deal of the dyspepsia and anæmia which are met with in daily practice. The ingestion of whole meal breads of the "Hovis" type materially assists in overcoming this tendency, and their use is not likely to be discontinued merely because, weight for weight, white bread contains a larger quantity of

assimilable nitrogen. At most the difference is but trifling, and would be amply compensated by an extra slice of bread and butter, and the passage of the undigested portion along the alime tary tract does not entail any appreciable strain on an organism which usually works at low pressure with an ample margin for contingencies.

The Deadly Low Flash Oil.

WE sincerely trust that the campaign against the deadly low flash oil will this year be carried to a successful issue. In the course of the year just closed no fewer than 100 persons lost their lives in this country directly in consequence of the explosive qualities of the dangerous oil. Our contemporary, the Star, which has done so much to bring public opinion to bear upon this question, has just published some startling facts relating thereto, and urges that the raising of the flash point is the most important social reform of the hour. Everyone who has paid the smallest attention to the subject must admit that legislation is imperatively demanded in this direction. The low-flash oil is not allowed to be used in America; the Russian manufacturers will not prepare it, and, significantly enough, the barracks, docks, and lighthouses in this country are never lighted with it. Therefore, apart from other testimony altogether, we should have thought that the Government ought to be satisfied with these facts, and raise no difficulty in acting upon them in the interests of the large population to whom mineral oil is a necessity.

"Private and Confidential."

WE have recently criticised the new policy of hugger-mugger and secrecy which has been developed in the administration of the General Medical Council since Sir William Turner succeeded the late Sir Richard Quain as President and Mr. Allen succeeded Mr. Miller as Registrar. We have entered our protest against a system of dealing with the business of an important public body in whispers or by hole and corner coteries, and we are glad to believe that the good sense of a large majority of the Council will be manifested against the methods sought to be established by a small party of the executive of the Council. We speak again to-day in order to repudiate emphatically any obligation to regard as confidential the official communications and reports set forth in the Council's programmes. It is not because the President or Registrar pleases to direct the printer to put "private and confidential" in the corner of the programme that they can thereby withdraw its contents from public knowledge and discussion, nor indeed is there anything in the agenda. of the Council which would justify secrecy except_ perhaps, the details of a case upon which the Council has to sit in judgment upon an indictment for The School Board or the "infamous conduct." County Council would have as much right as the General Medical Council to hide away the data for its public business and neither conclave has ever thought of doing so.

New Year Honours.

THE list of New Year honours comprises a fair number of representatives of the medical profession. To begin with, Sir Henry Thompson is awarded a baronetcy, which we hope he may be spared to enjoy for many years to come. Dr. Herman Weber carries off a knighthood, doubtless in return for his active collaboration in the anti-consumption movement. Sir Charles Cameron, the well-known Medical Officer of Health for Dublin, is made a C.B., upon which we offer him our congratulations; and Dr. T. E. Macpherson is created C.M.G. as a member of the Uganda administration. Of Indian officials Colonel W. P. Warburton, M.D., and Colonel D. Sinclair are nominated Companions of "The Most Exalted Order of the Star of India," while Lieut.-Colonel H. K. McKay and Major W. B. Browning are made Companions of the "Most Eminent Order of the Indian Empire." Dr. Plunkett O'Farrell, Commissioner of Control and Inspector of Lunatic Asylums in Ireland, is to be made a Knight. Lastly, the Queen has been pleased to approve the following appointments in the Order of the Ho-pital of St. John of Jerusalem in England, in recognition of distinguished services rendered during the plague epidemic in India: -

To be enrolled Honorary Associates of the Order:-Captain J L. T. Jones, Captain W. E. Jennings, (aptain A. F. W. King, Lieutenant W. J. Niblock. The following ladies have been selected as Honorary Serving Sisters of the Order: - Miss Lillian M. Robinson, Bombay; Miss Maud B. Kendall, Bombay; Miss Jane Eleanor Wheatley, Poona; Miss Emma Ann Moles, Poona; Miss Jessie E. Blair Hitchman, Sholapur; Miss Marion Hale, Cutch; Miss Harriet Jane Horne, Karachi; Sister Heriberta, Karachi; Mrs. Dyson, Surat.

The Proposed New Imperial University for India.

THE Provisional Committee appointed to carry out the preliminary steps to give effect to Mr. J. N. Tata's munificent offer for the foundation of a new University or "Research Institute" for India have interviewed the new Viceroy, with the object of securing his "sympathetic adhesion" to the scheme, towards the maintenance whereof the Government will by and bye be asked to contribute. Lord Curzon did not withhold his sympathy, but he showed diplomatic caution when asked to endorse the proposals laid before him. He evinced a desire to receive information on two very important pointsviz., whether, when the professors had been appointed, a sufficient number of pupils would be forthcoming to justify the new departure; and, secondly, whether, assuming an adequate attendance of students, posts could be found for them when they had fully availed themselves of the facilities which the institution would offer. Mr. Justice Candy, in his reply, made it clear that they looked especially to medical and sanitary science students for their alumni, and these, it was confidently anticipated, would find ample scope for useful and remunerative activity. Mr. Tata's offer of 30 lakhs of rupees is one which it would be a pity to allow to lapse, but a little caution on the part of the Government in committing itself

to approval of a particular scheme is perhaps commendable, as so many contingencies have to be borne in mind.

The Dublin Orthopædic Hospital.

A NOTICE appears in the Dublin newspapers of a somewhat unusual character, being an intimation that the executive of the Dublin Orthopædic Hospital has made application to the Board of Trade to register i as a limited liability institution. As is the manner of all who manage concerns which apply for official recognition, the executive of the hospital applies for most expansive powers empowering it to fit out hosp tals of unlimited extent, to pay the staff, to deal with the assets of the existing institution or any other assets which may accrue, and, in fact, to do a thousand things which, we apprehend, the existing executive has no intention of doing. We notice the public announcement only as a new departure, and reserve further criticism of the prospectus, in case such may seem necessary.

The Latest Sham Diploma.

A YORKSHIRE chemist, who, it would appear, is indisposed to submit himself to the excruciating ordeal of the examination for "Fellowship" of the Spectacle Vendors' Company, has improved upon the diploma granted by that august body. He announces himself as a "Doctor of Refraction" (Ref. Doct.) duly examined and graduated (in absentia) by the Philadelphia Optical College. This trustworthy institution says that he has "passed a most satisfactory examination in the theory and practice of refraction," and is, therefore, "entitled to the highest honours which the College can bestow," which is not saying much. But we await with interest some indication of the nature of the evolution described as "the practice of refraction."

The St. Petersburg Academy of Medicine THE Czar is delighted to honour this Academy, for he has addressed a letter, on the occasion of its centenary, eulogising and congratulating it. Several British physicians and surgeons have been chosen as honorary members, including Sir William Turner Sir William McCormac, Sir William Stokes, Mr. MacEwen, Lord Rayleigh, Dr. Thompson, and Dr Brunton.

THE meeting of the British Pharmaceutical Conference is to be held this year in Plymouth in the month of July.

A WAVE of salubrity is passing over Dublin just now. The total death-rate, which stood at 301 per 1,000 of the population in the first week of December, came down to 24'6 in the last week. Scarlatina, enteric, and diphtheria have all decreased in prevalence. The same may be said generally of the twenty-three town districts of Ireland, the aggregate death-rate of which came down, within the month, from 25.7 to 21.5,

Coroner v. Doctor.

A YOUNG man, while playing football, suddenly experiences pain in the abdomen and is taken to the hospital, where he is found to be suffering from strangulated hernia, and an operation was done, which, however, did not avert a fatal issue. The surgeon, naturally enough, delivered a certificate to this effect, but is called to account by the coroner (Mr. S. Langham), who holds that he ought to have been consulted before the death was certified. With all respect to Mr. Langham we cannot assent to his contention that the question whether or not death was accelerated by the football was one for the jury and not for the surgeon to decide. This is essentially a medical question, and the possibility of injury does not come in at all, so that Mr. Booker, the surgeon referred to, was acting well within the limits of discretion when he arrived at the conclusion that the case was not one calling for inquiry.

Menelik's Diversion.

MENELIK is devoting himself to watching surgical operations. In the hospital at Addis Ababa attached to the Russian mission there, he never loses an opportunity of watching the surgeons in their work. Their skill often calls forth from him expressions of admiration. His great desire is to act the part of an assistant, and, for example, hold the limb when an amputation is being performed, So much interest does he take in the proceedings that many times he has been heard to call out "Oya gut! Oya gut!' (admirable, admirable) as the surgeon displays some modern detail of surgical art. It is stated that he is kept informed of everything that takes place at the hospital, and that he never misses being present at an operation. Bravo, Menelik!

Army Medical Requirements.

THE Manchester Guardian says that the condition of the military Medical Service is far from being restored to equilibrium by the recent concessions to the demands of the officers, and that the anticipated rush of candidates has by no means satisfied the military authorities. It lays the blame for this upon the arrangement which, to economise the services of officers serving abroad, puts them on prolonged foreign service, and fills up their places at home with reserve men. This can scarcely be the true explanation of continued abstention of candidates, inasmuch as incoming candidates may be supposed to know not much and care less for the prolongation of the foreign service of the senior officers.

A Mismanaged Hospital.

SERIOUS allegations have been made public affecting the Guildford, Godalming, and Woking Joint Hospital Board. It seems that some newly appointed nurses had resigned on the ground that they had to live in the "scarlet fever kitchen," and sleep in the diphtheria room, while the general arrangements as to cleanliness, &c., left much to be desired. The allegations have been referred to a committee for investigation, and we trust the local

Press will take care that all legitimate grounds for complaint are removed. It should be borne in mind that nurses are entitled to special protection in view of the risks associated with their duties, and proper provision for their comfort and well-being ought to form an integral part of any hospital scheme.

Non-Compliance with the Notification Act.

Mr. John Patrick McNeil, surgeon, of Filmer Road, W., was fined at the West London Police Court last week for having neglected to notify a case of scarlet fever. He defended himself on the ground that he had not examined the child and was not aware of the nature of, the illness. We cannot extend the sympathy which we have sometimes expressed for the victims of this legislation to Mr. McNeil, who appears to have only himself to thank for this occurrence.

The Educated Herbalist.

A MAN died last week in Southampton after treatment for leprosy by a local herbalist, who admitted in the witness-box that he kept no books, did not know what he had given to the deceased, and could neither read nor write. Nevertheless he said that he had been in practice for sixty years, and had "cured not hundreds but thousands of patients." He got off scot free.

THE Standard of last Saturday records an extraordinary fatality within one family, and within a few days. On November 26th died, at Blackheath, the mother, æt. 80; on December 10th, suddenly at Yokohama, the youngest son, æt. 59; on the 21st, at Blackheath, the daughter, æt. 34; and on the 27th, in Australia, the third son, æt. 50. Obviously these deaths did not result from any epidemic, and had no immediate connection with each other, which makes the coincidence the more remarkable.

THE measures to be adopted to stamp out tuberculosis are to be the subject of a Congress which will be held in Berlin from May 23rd to 27th next.

Dr. James Hunter, of St. Catherine's, Linlithgow, has been presented with a testimonial expressive of affection and esteem, in the shape of a horse and brougham with harness complete, subscribed for by his patients.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE PAST YEAR.

The prominent feature in Scotland of the year just ended was undoubtedly the annual meeting of the British Medical Association, held at Edinburgh, in the last week of July. For nearly a year beforehand the various local committees had been hard at work arranging details, and were fortunate enough to see their labours rewarded in the success attendant upon the general run of the proceedings. Unfortunately, owing to the record attendance of members, and of their relations, many of the entertainments could not be rendered comprehensive enough to allow of all those desirous of taking part obtaining admission. It must be said, how-

ever, that there were always other functions available in place of the more popular attractions, which those unable to gain admission to the latter could attend. The impossibility of securing accommodation for more than a limited, though very considerable, number occasioned the ascription of blame to the arrangements, not to the real cause. Favoured with brilliant weather, received with admirable hospitality, honoured by numerous foreign guests, and provided with interesting topics for discussion, the meeting in Auld Reekie was a great success.

Otherwise not much of note has marked the passing year. The College of Medicine in Dundee has been providing for the professorships authorised by the Universities Commissioners on its affiliation with the University of St. Andrews. Occupants of the chairs in pathology, materia medica, chemistry, &c., having been elected.

Professor Fraser, of Edinburgh University was appointed in October to the president-hip of the Plague Commission sent by the Government to study the various scientific subjects connected with the etiology and prevention of that disease. The manner of his going and the arrangements made for the conduct of his work led to some acute frictional symptoms, both in the Edinburgh University and Royal Infirmary, which, however, rapidly subsided.

Influenza continued to attack many persons throughout the year, not at any time in severe epidemic form, but

in quite definite enough numbers.

Perhaps the meteorological conditions which have prevailed throughout the entire year form the most noticeable point. Although the occurrence of greater warmth than usual has been marked, the extraordinarily great decrease of any pronounced cold has been its chief characteristic. Up to the end of November the decrease in accumulated day degrees below 42 degs. F. amounted to nearly as much as 30 per cent. of the figure expected.

PLAGUE IN INDIA.

WE learn by the last mail that a marked decline of plague has been brought about throughout the Bombay Presidency, and at length we may hope for a rapid dis-appearance of the infection, at any rate in the epidem c form. This has been brought about chiefly by the more favourable reception given to inoculation, and to the efficacy of Professor Haffkine's newer prepared serum. He seems to have attained better success by appealing to the people through their own religious leaders. Wednesday last a very successful meeting was convened by the ex-Sheriff of Bombay, Adamjee Peerbhoy, at which some five thousand persons were present. The High some five thousand persons were present. The High Priest of the Bohras, whose word is law among his co-religionists, declared that there was nothing opposed to religion in the Professor's system, and therefore, his people could no longer object to inoculation as a preventive against the plague. The ex-sheriff and his son thereupon at once submitted themselves for inoculation, and a large portion of those present followed the good example. Professor Haffkine has, it appears, quite recently discovered a new and more promising mode of modified, and less disturbance of the general health follows. The success attendant upon the experiment of persuasion, will, it is hoped, facilitate and smooth the work of the medical profession in their efforts to stay the plague. This, however, is not the first success of the kind which has attended the exhausting labours of Professor Haffkine since he landed in Bombay some two or three years ago with the intention of studying cholers. When the plague found its way to the Byulla House of Correction, Bombay, the professors and students of the Grant Medical College volunteered to go to the jail and submit to inoculation in the presence of the prisoners. This had the effect of inducing the greater number of the inmates to follow their example.

Of the 175 uninoculated, Professor Haffkine reported "twelve took the plague and six died, while of the 148 inoculated, two only were attacked and both recovered." In the course of a few weeks some 8,000 persons submitted themselves for treatment. In another town,

Lower Damaun, 2100 persons were inoculated, while three times the number refused to submit, and between March and the end of May, 1,400 deaths occurred among the uninoculated. This large number of deaths, when compared with the 2,100 inoculated week by week, and supposing that they remained as susceptible to plague as the former, should have lost at least 332 individuals; whereas the actual number of deaths was only 36, representing a reduction of 89 2 per cent. A striking and convincing enough statement in favour of inoculation, giving encouragement to the hope that the termination of this third outbreak of plague is not far off.

The Plague Commission at Bangalore examined many witnesses as to the efficacy of Professor Haffkine's serum and the consensus of opinion as to its efficacy is considered to be very satisfactory. Two lady doctors, indefatigable at work among the women and children, spoke strongly in favour of inoculation. In the Northwest Provinces, the sanitary commissioner reports periodical outbreaks of a disease the symptoms of which correspond very closely to the less known form of plague, the pneumonic form. It is in most districts termed "Maha-mari." In the Mysore State there is little abatement of plague, which still shows a high deathrate. In the Hyderabad States there is no marked remission. In the Madras Presidency and the Central Provinces the disease, although pursuing a persistent course, is of a less severe character. In Bangalore, where for a time it raged so severely, a satisfactory and gradual decline is reported, while in Belgaum and Hubli it is fast disappearing. The Plague Commission held three sittings in Calcutta, and will make a second tour of the plague stricken districts of Bombay.

THE EXAMINING BOARDS AND PRELIMINARY EDUCATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir.—In the letter of the Registrar of the General Medical Council, which appears in your last issue, the incorrectness of the figures given in the report of the Education Committee with regard to cases of "deficiency in general education," reported by the Examining Boards of the "Navy, Army, and Indian Medical Services," is admitted, and it is explained that the limitation of these reports to the three services was due to an oversight in the drafting of the report which has, however, already been issued to the public in the half-yearly volume of the Council's minutes, has been made the subject of general comment in the Press, and has been officially communicated to this College. The oversight is, to say the least, unfortunate, as the report, in the form in which it was presented to the Council, was calculated to convey a most erroneous impression as to the extent of the alleged "deficiency in general education" attaching to persons who had registered as medical students on the certificates of this College.

It is now stated that the figures given in the report

It is now stated that the figures given in the report comprise the whole of the cases reported by the various Examining Boards, "including those for the Navy, Army, and Indian Medical Services," and that out of these 14 are those of candidates who had passed their preliminary examination at the College of Preceptors. With regard to the accuracy or otherwise of the figures given in the table in the registrar's letter, it may be sufficient to say that the total number of cases reported is, after the most careful examination of the published minutes, found to be, n t 58 but 84, or exclusive of cases not traced, 65. The number of the cases attributed to the College of Preceptors is apparently arrived at by including some cases in which under the old piecemeal regulation of the General Medical Council candidates were registered on certificates obtained from more than one examining body. As it would be impossible to say whether the subject of "English," in which the spelling test is usually included, was passed at one or the other exami-

complete of the several was a series.

nation, it seems only fair that all such cases should be eliminated, and the number for which the College of Preceptors may be held to be responsible would then be reduced to 11-11 cases in seven years out of a total of 2,133 candidates who, during that period have come on the Medical Students' Register by means of College of Preceptors' certificates. The proportion of cases traced to the College is therefore represented by the fraction 11-2,133, or about 1 per cent. The total number of medical students registered during the past seven years amounts to 12,526. The average of traced cases of deficiency would therefore be 1 in 193, or 1 per cent., the same proportion as that attributable to the College of Preceptors. But if only the number of those who have qualified on one or other of the junior or preliminary examinations in the United Kingdom be considered, the proportion would be 65 out of 8,467, or 1 in 130, or about

The proportion of reported cases of "deficiency in general education" among candidates who have qualified during the same period on certificates of the Irish Intermediate Education Board is represented by the fraction 3-166, or nearly 2 per cent., which is a somewhat different ratio from 11 2,133. Nevertheless, this examination is retained on the list, as are also the public entrance and other pre-graduate examinations of Trinity College, Dublin, with a proportion taken together of 4-150, or nearly 3 per cent The mere statement of these facts reduces the whole matter to its true proportions, and exhibits in the clearest light the triviality of the charge that has been brought against the College of Preceptors' examination, and made so prominent a feature in the report drafted, as was stated by the chairman of the committee, Dr. MacAlister.

I am, Sir, yours truly. H. W. Eve.

Dean of the College of Preceptors. College of Preceptors. Bloomsbury Square, W.C.

PRINCE OF WALES'S HOSPITAL FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR, - A curious thought occurs to me with regard to the distribution of this Fund which is generally supposed to be under the direction of Sir Henry Burdett. gentleman has been for many years an uncompromising advocate of uniformity in relation to all hospital matters. and publications are issued under his auspices for the furtherance of this praiseworthy principle.
One is forced to ask what is the basis of uniformity

which has guided the award to two hospitals—("the London" and "Guy's")—of a third of the whole sum intended—at least, according to the ideas of subscribers for the relief of some eighty or ninety.

I am, Sir, yours truly,

January 2nd, 1899.

X.

BOGUS MEDICAL DIPLOMAS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR, - It is certainly alarming to medical practitioners who have industriously spent the greater part of their lives and fortunes in acquiring a license to practice their profession, to see day after day companies and mechanics such as the Spectacle makers and nurses of the Obstetrical Society successfully placing themselves before the public—so far as the general public can judge by their high sounding titles—with Fellows and Members of the different departments or branches of the Medical Profession. It is my experience when the public hear of a midwifery nurse with a diploma that they regard her in every respect, owing to her training of which the diploma is accepted as a guarantee, to be as capable of seeing a woman through the intricacies of her confinement as any registered medical practitioner, and needless to add this little simple-minded fallacy has the nurses fullest connivance.

It is to be feared, too, that ophthalmic surgeons, with their hard earned Fellowships and degree honours, will experience similar trouble from the Diplomate or Fellow of the Spectacle Makers' Company, and that the titles

will be simply sought in many cases to parade before the public with a view to deception, However, anything that would tend to misconstrue the honour attached to the present day hard-earned medical or surgical Fellow-ship is to be deprecated in itself, but if "faked" honours of the obstetrical and spectacle class should lead, as some would suggest, to the abandonment of such justly honourable titles, the result would be an enormous loss to medical education, as with such post-graduate honours would disappear all incentives to further medical education, and members of the prefession would have to content themselves with the diplomas of their final students' examination. Unqualified assistants are a thing of the past but the Spectacle Makers' Company and Obstetrical Society are reviving them in an infinitely worse and more dangerous form. Few. if any, of the unqualified assistants were ever so ignorant of the science of their business as the midwife with the diploma, why then not allow them to get a diploma in this branch of the profession and practice it? Why should the unqualified assistant labour under sexual disabilities?

I am, Sir, yours truly,

MEDICUS.

Literature.

CATTLE TUBERCULOSIS (a).

This little work is all it pretends to be, and more, since it is not only a guide to laymen, but also to medical men and veterinary surgeons, for it gives them in a concise and readable form all they require to know about

this dire maledy for everyday practice.

It points out very truly that the general professional man and the public are just beginning to wake up to the importance of this disease respecting public health. A fact which Professor Gerlach, late director of the Berlin Veterinary School tried to bring prominently before the public more than twenty years ago from the experiments he had then carried out; and this was followed up in this country by a pamphlet on "Tuberculosis from a Sanitary and Pathological Point of View," by Dr. George Fleming, F.R C V.S., late Principal Veterinary Surgeon to our Army in 1881. Dr. Creighton, we believe, conclusively demonstrated some fifteen years or more ago the identity between human and bovine consumption, still, it is only within the last few years, we may even say months, that this has been generally accepted. However, we think a perusal of this little work of 77 pages, will do a good deal to convince those who still have any doubts on the subject, if they will only take the trouble to read it, especially with regard to the dangers of f eding young children and animals on milk containing the bacilli of tubercle, which hitherto has received so little attention from those in authority.

It is divided into chapters dealing with the causes, symptoms, and prevention of tubercle, the inspection of such meat, and how tuberculous carcasses should be used, and last (but not least to the owners of such animals) the necessary means of preventing any very great loss, and stamping the malady out from our herds.

There are also some very instructive statistical tables showing the percentage of animals affected, as well as its distribution in the various organs of the body. Altogether the work is carefully collected and put together, in fact it is a multum in parvo on tuberculosis, and we strongly recommend all those connected with public health, stock raising, and dairy work to obtain a copy and carefully read it.

TAYLOR'S MANUAL OF THE PRACTICE OF MEDICINE. (b)

This popular text-book of the Practice of Medicine has now expanded to the dimensions of 1,002 pages. The

(a) "Cattle Tuberculosis. A Practical Guide to the Farmer, Butcher, and Meat Inspector," By T. M. Legge, M.A., M.D., and Harold Sessions, F.B.C.V.S. London: Bailliere, Tindail and Cox. 1898. Price 2s. 6d. net.
(b) "A Manual of the Practice of Medicine." By Frederick Taylor, M.D., F.R.C.P., Physician to, and Lecturer on Medicine at, Guy's Hospital, &c., &c. Fifth edition, London: J. and A. Churchill. 1898.

continuous popularity of its progress is the very best evidence that can be supplied of its importance as a guide

book to the student and the practitioner.

Besides the revision of the general text, the "introductions to Diseases of the Nervous System and to Diseases of the Blood, and the subjects of Aphasia and Ringworm," we have additions to the text of the former editions in the articles on Glandular Fever, Diver's Paralysis, Enthromelalgia, Angeioneurotic Œdema, Hypertrophic Pulmonary Osteo arthropathy, and Tubercle of the Skin. A separate section is devoted to Diseases of the Mediastinum; and Filarial Diseases and hæmo-globinuria have been transferred to Diseases of the Lymphatic System and of the Blood respectively.

In addition to the textual modifications, by which the author has carefully and conscientiously brought his subjects up to the present standard of scientific attainments and practical requirements, we are told in the closing paragraph of the preface that "It has been thought advisable to make a change in the style of the printing of the work, and it is hoped that the larger p ge, with a clearer type, will be found an improvement. We congratulate Dr. Taylor on the result of his labours, and feel assured that this convenient and beautifully printed manual will continue to enjoy its well-merited

Medical Aews.

Medical Reform.

AT a well-attended meeting of practitioners of Rochester, Chatham, Strood, New Brompton, Sittingbourne, and districts, held at St. Bartholomew's Hospital on the 23rd ult., at which a paper was read by Mr. R. B. Ander son, F.R.C.S., explaining the policy of the Corporate and Medical Reform Association, the following resolutions were enthusiastically and unanimously passed: -" That were encutassisted by and unanimously passed:— I not this meeting of registered medical practitioners of Rochester, Chatham, Strood, New Brompton, Sittingbourne, and district, supports the principles and policy of the Corporate and Medical Reform Association, Limited, and will co-operate collectively and individually, by every constitutional means, in promoting its measures" "That this meeting of registered pracresolves itself into a district society of the Corporate and Medical Reform Association, Limited, for that district." A memorial to the General Medical Council on the subject of the illegal granting of certificates having been signed by the twenty-three members present, the meeting terminated with votes of thanks to Mr. Anderson and the chairman, Mr. Vincent Bell.

The Mortality of Foreign Cities.

THE following are the latest official returns, and repre sent the last weekly death-rate per 1,000 of the several populations:—Calcutta 22, Bombay 40, Madras 41, Paris 18, Brussels 19, Amsterdam 16, Rotterdam 17, The Hague 13. Copenhagen 16, Stockholm 16, Christiania 19, St Pethisburg 24, Moscow 30, Berlin 16, Hamburg 16, Dresden -, Breslau 22, Munich 26, Vienna 20, Prague 26, Buda-Pesth 20, Trieste — Rome 15, Turin (10 days) 14, Venice 19, Cairo —, Alexandria — (including Brooklyn) —, Philadelphia 16. New York

Royal London Ophthalmic Hospital.

SIR SQUIRE BANCROFT has kindly promised to tell the story of Charles Dickens' Christmas Carol at St. Martin's Town Hall on Thursday afternoon, January 12th, at 3 o'clock in aid of the Royal London Ophthalmic Hospital. The Right Hon. Sir John Lubbock, Bart.. M.P., F.R.S., &c. (president of the hospital) will preside. Tickets can be obtained from the Secretary, Royal London Ophthalmic Hospital, Moorfields, E.C.

Vital Statistics.

THE deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 17.8 per 1,000 of their aggregate populations which is estimated at 11,218,378 persons in the middle of this year. The deaths registered in each of the last four weeks in the several towns alphabetically arranged, corresponded to the following annual rates per 1,000:-

Birkenhead 14, Birmingham 19, Blackburn 17, Bolton 21, Bradford 16, Brighton 18, Bristol 17, Burnley 13, 21, Bradford 16, Brighton 18, Bristol 17, Burnley 13, Cardiff 10, Croydon 13, Derby 13, Edinburgh 18, Glasgow 18, Gateshead 15, Halifax 19, Huddersfield 14, Hull 15, Leeds 17, Leicester 12, Liverpool 22, London 17, Manchester 23, Newcastle-on-Tyne 18, Norwich 15, Nottingham 20, Oldham 20, Plymouth 18, Portsmouth 14, Preston 21, Salford 25, Sheffield 18, Sunderland 17, Swansea 30, West Ham 14, Wolverhampton 12. The highest annual death-rates per 1,000 living as measured by last week's mortality were ... From living, as measured by last week's mortality, were :- From measles, 26 in Bolton and 29 in Nottingham; from whooping-cough, 1:1 in Halifax and 1:3 in Preston; from "fever," 1:0 in Salford, 1:3 in Brighton and in Bolton, "fever," 10 in Salford, 13 in Brighton and in Bolton, and 14 in Norwich: and from diarrheea, 11 in Plymouth. In none of the large towns did the death-rate from scarlet fever reach 1 per 1,000. The 115 deaths from diphtheria included 46 in London, 17 in Leeds, 10 in Swanses, 7 in Sheffield, 6 in West Ham, 6 in Liverpool, 4 in Brighton, and 3 in Cardiff. No death from small-pox was registered in any part of the United Kingdom.

PASS LISTS.

University of London.

The following are the official lists of candidates who assed the examinations this month under the specified headings:-

M.D. Examination.—Medicine.

M.D. Examination.—Medicine.

Percy Edward Adams, Arthur Percy Allan, B.S., John Hervey Bodman, B.S., William Francis Victor Bonney, B.S., John Arthur Oswald Briggs, Maud Mary Chadburn, Frederick Nesfield Cookson, Montague Dixon, B.Sc., Bobert William Dodgson (Gold Medal); Edward Guy Dru Drury, B.S., George Richard Elwin, Arthur Henry Evans, B.S., John William Haines, B.S., Arthur Heath, Alfred Howell, Tom Harold Hunt, B.S., James Hussey, William Henry Jewell, B.S., John Liewelyn Jones, B.S., Cuthbert Henry Jones Locyker, B.S., Antony Alexander Martin, B.S., Elizabeth Jane Moffett B.Sc., Eldon Pratt, George Basil Price, B.S., William Thomas Gordon Pugh, B.S., Alfred William Sanders, William George Savage, B.Sc., Edmund Ivens Spriggs; William Henry Butter Stoddart, B.S., Edmund Ivens Spriggs; William Henry Butter Stoddart, B.S., Francis Hugo Thiele, B.Sc., Evan Homas, B.S., Edwin Josiah Toye, B.S., B.Sc., Ethel May Vaughan, B.S., Wilfred Brougham Warde, Thomas Henry Wells.

B.S. Examination. - First Division.

Thomas Varley Cunliffe, Joseph Geo. Emanuel, B.Sc., John Preston Maxwell Donald John Munro, Winifred recretan Patch, B.Sc., Ernest William Spink.

Second Division.

Louisa Garrett Anderson, John Smedley Boden, Elizabeth Honor Bone, Harold Wilson Bruce, Arthur Stanbury Cobbledick, Ernest Coleman, Lucinda Catherine E. Forster, Leonard Gilbert, Ernest Geo Leopold Goffe, Arthur Stanley Green, Joseph Percy Ilall. Lionel Edwin Charles Handson, Harry Edward Hewitt, John David Jenkins, Jn. Cyril H. Leicester, M.D., B.Sc., Frank Charles Lewis, James Laidlaw Maxwell Mary Elizabeth Pailthorpe, Francis Riley, Harry Sinigar, M.D., Florence Ada Stoney, Russell Henry Jocelyn Swan, Walter Hy. Maxwell Telling.

M.S. Examination.

Charles Herbert Fagge, Charles E. Mackenzie Kelly, M.D. John Stretton Sloane, B.Sc., William Turner.

M.B. Examination.—Examination for Honours.-Medicine.

First Class.—Thomas Jeeves Horder, B.Sc., Gold Medal, St. Bartholomew's Hospital: Henry Gwynne Lawrence, cholarship and Gold Medal, St. Mary's Hospital; Russell Henry Jocelyn Swan,

Gold Medal, St. Mary s Hospital; Bussell Henry Jocetyn Swal, Guy's Hospital.

Second Class. - Frederick Fenn Elwes, Middlesex Hospital; William Layard Griffiths. B.Sc., University College; Frank Charles Lewis, St. Mary's Hospital.

Third Class. - Elizabeth Honor Bone, Royal Free [Hospital; Harold Douglas inger, St. Thomas's Hospital.

Obstetrio Medicine.

First Class.—Thomas Jeeves Horder, Gold Medal, St. Bartholomew's Hospital; Henry Gwynne Lawrence, St. Mary's Hospital; J. Preston Maxwell, Scholarship and Gold Medal, St. Bartholomew's

Second Class — Joseph George Emanuel, B.Sc., Mason C. and Queen's and Gen. Hospitals, Birmingham; Frank Charles Lewis, St. Mary's Hospital.

Third Class.—Victor Evelyn Collins, Guy's Hospital; Donald John Munro, Guy's Hospital; Henry Peet, Yorkshire College; Arthur Geo. Grant Plumley, Med. Sch. and Univ. C. Bristol and Guy's Hospital; Francis Biley, Westminster Hospital.

Poreceio Medicine.

First Class.—Victor Evelyn Col ins, Guy's Hespital; Thomas-Jeeves Horder, Gold Medal, St. Bartholomew's Hespital.

Second Class.—Leonard Gilbert, St. Thomas's Hespital; Arthur Stapley Green, R. C. Surg. Ireland and Meath. Hespital; Harry Edward Hewitt, St. Thomas's Hospital; Francia Seymour Liny I, St. Mary's Hospital; Harold Douglas Singer, St. Thomas's Hospital;

Aotices to Correspondents, Short Tetters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Authors of papers requiring reprints in pamphlet form after they have appeared in these columns can have them at half the usual cost, on application to the printers before the type is broken up.

RHADING CASES.—Cloth board cases, gilt lettered, containing wenty-six strings for holding the numbers of The Medical Press AND CIRCULAR, may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through

LOCAL REPORTS AND NEWS.—Correspondents desirous of draw. ing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

"MUSIC HATH CHARMS," ETC.

"MUSIC HATH CHARMS," ETC.

A CORRESPONDENT sends the following feetive effusion:—It has been suggested that music might prove a useful adjunct (in some cases, at least) where the usual routine treatment by medicine had not proved satisf ectory. I venture to suggest the following well-known airs as being suitable for the cases soumerated, viz.:—

Retarded labour from inertia ("Coming through the rye").

Chronic aphonia ("The lost chord").

Melancholia ("The heart bowed down").

Epilepsy ("Let me like a soldier fall").

Cases of chronic deafness ("Come back to Erin").

Pyrexia ("McCoolin").

Cases of doubtful diagnosis ("Oh dear, what can the matter be?")

INDIGNAES.—You are quite right in your supposition. Any private person is entitled to have an article analysed by the Public Analyst, on payment of a fee not exceeding half a guinea (Sale of Food and Drugs Act, 1875, Sect. 12—14). At the time of purchase he must inform the vendor of his intention to have the article analysed, and must offer to divide it into three parts, to be then and there separated, marked, sealed or fastened up. One portion is then to be handed to the vendor, one sent to the analyst, and the third retained by the purchaser. If the article be found adulterated such private purchaser may prosecute. Should the local authorities neglect their duty it is thus possible for a private individual to set the law in motion in the interests of the public Before undertaking any such step, however, he will do well to make himself thoroughly acquainted with the conditions and outlines of the special Act above quoted.

REGIUS.—The end aroun to stamp out quacks or quackery has never been remarkably successful. Even before the days of Henry VIII, the charter of the Royal College of Physicians of London gave them power to restrain all pe-sons from practising the faculty of medicine in the City of London or within seven miles thereof without the college licence, under a penalty of 25, and by a statute in the reign of Henry VIII, which confirmed this charter it was further enacted that "No person shall be suffered to exercise or practise in Physick through England without a licence from the college, except he be a graduate of Oxf. Ind or Cambridge, which hath accomplished all things for his form without any grace," but it is to be noted that n mention is made of any penalty. Somewhat wimits r provisions were made as to the practice of surgery, but whether these antiquated statutes could now be enforced is a matter which experience alone can settle.

Meetings of the Societies and Lectures.

WEDNESDAY, JANUARY 4TH.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by Dr. Lea, Dr. Addinsell, and Dr. J. Philips. Papers:—Dr. Donald: A Case of Ectopic (Intra-ligamentous) Gestation at the Seventh Month in which the Fœtus was Extracted by Vaginal Incision.—Dr. D. Robinson: Vulval Discharges in Children.

THURSDAY, JANUARY 5TH

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne, Street, Edgware Road), 8.30 p.m. Mr. H. Marsh: On the Subsequent History of Cases in which Adhesions have formed in Joints, the Peritoneal Cavity, and other parts.

FRIDAY, JANUARY 6TH.

WEST LONDON MEDICO-CHIBURGICAL SOCIETY (West London Hospital, Hammersmith W.).—8.30 p.m. Mr. R. Lake: The Treatment of Laryngeal Phthisis.—Mr. J. R. Lunn: Two C-sees of Optic Neuritis associated with Mastoid Disease.—Dr. J. Allan: A Series of Twelve Tracheotomies for Laryngeal Diphtheria in Ymnog Children, with Nine Recoveries.

LABYNGOLOGICAL SOCIETY OF LONDON (20, Handway Square, W.).—4.30 p.m. Annual General Meeting. Election of Officers and Annual Reports. Cases will be shown by Dr. S. Spicer. Dr. D. Grant, Mr. C. Symoods, Dr. B. Baron. Mr. M. Agar, Dr. Tilley, Sir Pelix Semon, Dr. W. Williams, Mr. W. Wingraye, Mr. A. Thorne, Dr. St. Clair Thomson, Dr. W. Hill, and others. 8 p.m. Divner at the Orfa Revysl. Dr. St. Clair Th

BOYAL ACADEMY OF MEDICINE OF IRELAND.—Dr. Purefoy: Mytmatous Uterus. Dr. Glenn: Intra-ligamentous Cyst of Left Ovary; Tuberculous Tube and Cystic Right Ovary; Removed by Abdominal Section. Dr. Jellett: Mymatous Uterus undergoing Carcinomatous Degeneration. removed by Penhysterectomy. Papers: 1. Report of Rotundo Hespital Maternity for past year. 2. Report of Rotundo Gymecological Hospital. 3. Dr. More Madden: Treatment of Malignant Disease of the Uterus.

TURSDAY, JANUARY 10TH.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck Street).—4 p.m. Dr. Harry Campbell: Cases of Locomotor Ataxy, with Observations on its Treament.

Vacancies.

Birmingham City Asylum,—Junior Assistant Medical Officer unmarried. Salary £100° a year, with board lodging, &c...
County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary commencing at £100 per annum, with furnished apartments, board, attendance, and washing.
Pinsbury Dispensary. Goswell Road. London.—Resident Medical Officer for one year. Salary £100 per annum, with furnished residence in the institution, attendance, coals, and gas.
Govan District Asylum.—Junior Assistant Medical Officer. Salary £100 a year, with board and residence. Applications to the Medical Superintendent, Hawkhead Asylum, Paisley.
Kensington Dispensary.—Resident Medical Officer, unmarried. Salary £125 per annum, with furnished apartments, coals, gas, and attendance. Applications to the Honorary Secretary, 21, Lower Phillimo'e Place, Kensing'on. W.
National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen Equare, London—Pathologist. An annual honorarium of 50 guineas. Also House Physician. Salary £100 per annum.

Nottingham General Hospital.—House Physician. Salary 2100, rising to £120, with board, lodging, and washing.

Royal Southern Hospital, Liverpool.—Resident Junior House Sur-

Royal Southern Hospital, Liverpool.—Resident stated from the seasons geon. Salary 260 per annum.

Royal United Hospital, Bath.—House Surgeon. Salary at the rate of £60 per annum, with board, lodging and washing. Somerset and Bath Lunatic Asylum. Cottord, Taunton. Assis ant Medical Officer for five years, single. Salary commencing at £120 per annum, with furnished apartments, board, fuel, librated and washing.

Medical Officer for five years, single. Salary commencing at £120 per annum, with furnished apartments, board, fuel, lighting, and washing.

Sunderland Informary.—House Physician. Salary £30, rising £10 annually to £100 with board and residence.

Township of Toxteth Park.—Senior Assistant Medical Officer for the Workhouse and Informary. Salary £100 per annum, with board, washing, apartments. Applications to the Clerk to the Guardians, 15, high Street, Liverpool.

Appointments.

BUED, CYEIL P., M.R.C.S., L.R.C.P. Assistant House Surgeon for the Salop Infirmary, Shrewsbury.

COLE, J. W. E. L.R.C.P.Lond., M.R.C.S., Assistant Medical Officer for the Infirmary of the City of London Union.

DAVIES, RICHAED, M.D., Ch. M. Belin., M.R.C.S., L.R.C.P. Lond., Medical Officer of the Cheltenham Union Workhouse.

GAED, HENEY, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Medical Officer for the Northern District of Devonport.

HOGG, J. B., L.R.C.P., L.R.C.S. Ed. Inspector of Hospitals for the Insane in Queen-land and Medical Superintendent for the Goodna Hospital for Insane, Queensland.

HUTCHINSON, M. M. L., L.R.C.P., L.R.C.S. Irel., Medical Officer for the Buckhurst Hill Sanitary District of the Bpping Union.

JONES, R., L.K.Q.C.Irel. L.R.C.S., Health Officer and Public Vaccinator for Englehawk, Victoria, Australia.

MACDONALD. M., M.B., Ch.B.Glasg., Officer of Health for the Burgh of Greenack.

MAGGREGOR, G. R., M. D.Aberd., Medical Officer for the Bollington Sanitary District of the Macclesfield Union.

MELLAND, C. H., M.H. Lond., M.R.C.S., Resident Medical Officer for the Bollington Sanitary District of the Macclesfield Union.

MELLAND, C. H., M.H. Lond., M. R.C.S., Resident Medical Officer for the Workhouse and the First Sanitary District of the Dursley Union.

Scholeffeld, G. E., M.D.Ed., D.P.H.Vict., Medical Officer of Health by the West Lancashire Rural District Council.

Births.

WEIGHT.—On Dec. 24 h, the wife of W. Southey Wright B.A., M.R.C.S., of Park View, Carshalton, of a son.

Beaths.

MAGORIS.—On Dec. 26th, at the Seamen's Hospital, Royal Albert Docks, Nicnolas Magoris, M.D., aged 30, late Surgeon to the P. and O. Steam Navigation Co.

The Medical Press and Circular.

No. 2.

Original Communications.

THE SURGERY OF THE GALL-BLADDER.

By J. McARDLE, F.R.C.S., Lecturer in Surgery, St. Vincent's Hospital.

(Continued from page 644, last vol.)

HYDATID CYST SIMULATING DISTENDED GALL-BLADDER AND CAUSING OBSTRUCTION.

Case VI.—Miss C. B. set. 24, came under my care suffering from severe pain in the abdomen, and chiefly in the right lumbar region. She had had severe vomiting, and had become greatly emaciated. The bowels could not be pot to act properly, although flatus passed occasionally. On examination I found a tumour occupying the right hypochondriac region, and extending downwards to the anterior superior spine; it was tender on pressure, dull on percussion, and could be moved upwards and laterally with free-

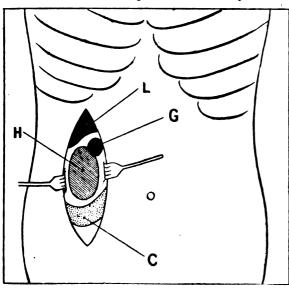

Fig 6.

dom, but could not be drawn downwards below interspinous line. It moved up and down with the respiratory act. An indistinct fluctuation could be detected, and, although the tumour felt ovoid, the dulness was encroached upon below and on the left side by an irregular area of resonance. Owing to the ease with which the tumour could be felt through the quadratus lumborum it was thought to be of renal origin, but bimanual examination under ether enabled me to discover the kidney, normal in position and size, lying well behind and on a higher level than the tumour. There had been no jaundice, no history of recurring colicky pains, and so gall-stone trouble was unlikely. I decided that it was a hydatid connected with the under surface of the liver, or a distended gall-bladder.

Operation.—Assisted by Mr. Tobin and Dr. Alfred Smith, I opened the abdomen in the right semilunar line. I found the omentum adherent to the abdominal wall, and with some difficulty detached it, to find that it was closely connected behind to the tumour. So firm were the adhesions that I was obliged to resect a portion of the omentum. On turning down the stump of the omentum the tumour was exposed. It proved to be a hydatid as large as a fair sized melon, and somewhat like it in shape. It was surrounded, as in Fig. 6, by the colon, which was firmly adherent to its lower and left surface. The gall-bladder presented, as at G. Fig. 6, green and distended, and the tumour could be traced to the fissure of the gall-bladder, where it compressed the cystic duct and caused partial obstruction, leading to the distension observed.

The cause of intestinal trouble was very apparent when the colon (C, Fig. 6) was exposed. I found it dark purple in colour and firmly adherent to the lower and left lateral aspects of the tumour. The adhesions were very vascular, and during separation, rather free bleeding occurred. Most of this was controlled by packing with very warm gauze sponges, but at several points double ligatures were necessary before section of unusually firm attachments could be carried out. The most difficult part of the operation was the separation from the liver and gall-bladder, and one very large vessel—a branch extending from the cystic artery—was with difficulty secured; at the root of the tumour many vessels required ligature. When the tumour was removed a great cavity existed below the liver, into which the colon bulged. This cavity was tamponed with iodoform gauze, and the greater part of the abdominal wound closed with silk-worm gut sutures.

Owing to the low vitality and the protracted nature of the operation the patient did not rally rapidly, but on the second day after the procedure she seemed nothing the worse of its gravity. For some days there was rather free sero-sanguineous discharge. This ceased after removal of the gauze drain, and on the thirteenth day, when the sutures were removed, the wound was soundly healed.

From this time recovery was rapid, and since there has been no vomiting or intestinal distress of any

CASE VII.—Miss B., at. 22, came under my care on March 3rd, 1898. She had been operated on several times for the purpose of relieving what appeared to be at one time ovarian trouble, at another intestinal. Obtaining no relief she consulted me, and on examination I found her looking at least 35 to 40 years old, dragged, worn and ashen grey, in appearance she was much wasted and complained that after any exertion acute abdominal pain set in a little above and to the right of the umbilicus, and any food, especially meat, also brought on this pain. There was not much vomiting, but she suffered greatly from flatulence, and after the pain persisted for any length of time an uneasy sensation occurred between her shoulders and down her back; the urine was loaded with lithates, and she found it very hard to overcome persistent constipation. There was deep-seated tenderness under the right costal arch and in this neighbour hood an ill-defined tumour could be felt.

Operation: I made a vertical incision in the right semilunar line hree inches in length. Immediately on opening the peritoneum the gall-bladder presented in the wound, it was greenish in colour and much larger than normal I laid it open freely there was a copious discharge of fairly normal bile, and with the flushing scoop I removed 24 good sized calculi. The course of this case was uneventful, the wound was completely he aled n the third week, and from the date of the operation until the present she has never had the slightest return of the old trouble, and now eight months after operation she has gone back to her proper age so far as her appearance goes.

so far as her appearance goes.

Case VIII.—Mrs. C. B. was sent to me by Dr. Moorhead, of Tullamore, on May 14th, 1898. For years she had had recurring attacks of abdominal pain, of late these had been so frequent and annoying that her life became intolerable. Jaundice was very marked, and the history showed that it had varied in intensity. During the last few months she was at times perfectly free from pain, but suddenly a fit of vomiting would come on to be followed by intermitting attacks of violent pain under the right costal arch, free purgation, followed by morphia, used to relieve her, but only temporarily. Worn out with distress, she consented to have anything done that would give her a chance of relief. She was so wasted that many people thought that the jaundice was the result of carcinoma of the liver, but on examination found the liver dulness normal, and I could detect the gall-bladder projecting as low as the umbilicus.

the gall-bladder projecting as low as the umbilicus. Operation on May 20th.—Expecting to find many adhesions, I made a free opening after Billroth's method, and thoroughly freeing the colon, pylorus and the gall-bladder, I drew the latter, which was very much enlarged, well into the wound, and passing my finger along the duct I discovered a large stone fixed therein. I now opened the gall-bladder, and gave exit to a considerable quantity of muco-pus scarcely stained with bile, with this twenty-four fair-sized calculi came away, and after some difficulty I was enabled to remove the one which was fixed in the duct. The cause of difficulty in its removal was the peculiar projections which were fixed in the mucous membrane. This stone is depicted at A Fig. 7. For many days bile discharged in very large amount, and owing to the low vitality of the patient several weeks elapsed before recovery was complete, but from the moment the gall-bladder was emptied pain ceased, and a gradual restoration of health set in, and she left hospital well on June 17th.

CASE IX.—On May 30th, 1898, Mrs. L., æt. 47, was sent to me by Dr. Keelan, of Dunler, who diagnosed the case as one of gall-stones. The history extended over some years and the attacks were typical only that the pain was of a more excruciating character than usual. This I found as in Case No. XI. was due to the fact that the calculi were mulberry in shape (B Fig. 7), and they must in passing have greatly irritated or even torn the gall-ducts, owing to their roughness. Jaundice had been intermittent in this case, and when she came to me she was deeply bile stained.

Operation, June 3rd.—In this case I adopted Kocher's incision and on reaching the gall-bladder I found much difficulty in bringing it to the surface Its walls were thick and greyish blue in colour. Fixing it with toothed forceps, and packing well round it with gauze sponges I opened it freely, much semigelatinous material came away, and flushing out with sterile water removed seven mulberry calculi. They were very rough, and no trace of facet on any of them (vide Fig. 7). I sutured the peritoneum carefully round the wound of the gall-bladder, as it could not be brought to the surface, then closed the remainder of the peritoneal opening by buried suture, a long strip of iodoform gauze was now placed in the gall-

bladder and the rest of the abdominal incision was closed with silkworm-gut suture. Recovery was very rapid, the patient being up and about on the 11th day. She left the hospital on June 23rd the wound being thoroughly healed.

being thoroughly healed.

CASE X.—Mrs. M. C., et. 38, came under my care on November 1st, 1898, complaining of persistent pain under the right costal arch, it was particularly marked after eating meat, and came on about half an hour to an hour after meals. There was rarely any vomiting, but still patient gradually emaciated and became exceedingly weak. She also complained of pains across the umbilical region, especially after my exertion. Double ovariotomy had been performed on her by Lawson Tait some years ago, since that time the pains above referred to seemed to increase. She now consulted Treves, Cullingworth, and others, all of whom believed her troubles were due to the adhesions. Laparotomy was twice carried out on her, adhesions being broken down on each occasion, but without any relief of the symptoms. When she consulted me her face was dark in colour, drawn and anxious-looking, the very sight of food caused nausea, and the pain was so great after taking anything that she practically avoided nourishment altogether. examination I found the right rectus muscle rigid,

Fig. 7.

there was no tenderness on pressure, the stomach was resonant and much distended. The pain had now become paroxysmal in character, and looking upon it as a case of gall-stones, I opened the abdomen by Kocher's subcostal incision; I found numerous adhesions of the colon to the lower edge of the liver and front of the pylorus, and on reaching the gall-bladder I found it distended, here and there a stone could be felt floating in the fluid. On examining the cystic duct I found an ovoid calculus impacted as shown in Fig. 8. I opened the gall-bladder in the ordinary way, and removed a number of medium-sized facetted calculi. Grasping the duct between the index and middle finger of the left hand and insinuating a blunt-pointed elevator between the large calculus and the wall of the duct I was enabled to prize it into the bladder and remove it; now bile welled up into the wound showing that the duct was free, and after flushing the gall-bladder thoroughly with sterile water I sutured it in the ordinary way to the abdominal wound. There was a copious discharge of bile for the first few days, this

gradually lessened, and by the third week the wound was fairly healed. From the day after the operation the patient had no pain whatever, and in the fourth week she left for home able to take her ordinary meals without experiencing any inconvnnience. The large stone found in the duct is depicted at c. Fig. 7. It is rough and round at both ends, there is an attempt at facetting.

CASE XI.—Mrs. S., set. 30, consulted me in February, 1898, about an uneasy feeling she had in the epigastrium which at times became unbearable. Her friends noticed that when this pain was severe profound collapse occurred, and for days after she was very prostrate. They did not at the time mention to me that the seizures were epileptic in form; there was no jaundice, but before these attacks vomiting was very troublesome. On examination of the abdomen I found a fulness under the right costal arch, which disappeared on elevating the hips and making pressure from the front; it would suddenly reappear when the patient was raised into the erect posture. The diagnosis I made at this time was that

Fig. 8.

the attacks were brought on by gall-stones of very irregular outline being caught in the ducts in their passage to the intestines. The doctor in the country did not see his way to agree with this diagnosis, and so the patient was kept under observation by him until early in November, 1898, when she came to Dublin looking very much worse than when I first saw her. A few days after her arrival in town I was called to her hotel to see her in one of these attacks, I found her in a most deplorable condition, with a pulse too quick and small to count, a dark ashen grey look in her face, screaming with pain, which came at intervals and caused her to twist into a heap on the bed. Under the influence of morphia this pain subsided, and on November 20th I admitted her to the private hospital, No. 10, Holles Street, where on the 23rd I opened the abdomen by an oblique sub costal incision. There were numerous adhesions of the gall-bladder to the abdominal wall and the colon; on drawing the gallbladder into the wound it was exceedingly dark in colour and very tense; on opening it a black gela-tinous mass rolled out into a tray placed to receive it, and with it many gall-stones were expelled, the shape of these is depicted in Fig. 9. Several of them were fixed in the cystic duct, and owing to their shape I had great difficulty in removing them; ultimately with the aid of a scoop I was enabled to displace them and flush them out. After thorough flushing I sutured the gall-bladder to the wound as usual, laid a short drainage tube and closed the inci-

treatment. Next day found her with a normal temperature. Since that time there has been no recurrence of the troubles which made her life so miserable before. In this case I found a large stone encysted in the wall of the gall-bladder, as shown in

drawing.

CASE XII.—Mrs. H. came under my care on March 1st, 1898, complaining of intense pain in the right side and extending inwards as far as the umbilicus. This pain was greatly increased after walking for any length of time, and was frequently attended by vomiting of considerable quantities of bile-stained fluid. The bowels never acted without physic, and sometimes many days elapsed before aperients would have any effect. She was greatly cyanosed, was very breathless and corpulent. Examining under ether I found the right kidney displaced inwards and forwards but could not detect the gall-bladder, although I had suspected trouble there. On March 11th I made a long oblique sub-costal incision. The liver projected below the ribs a considerable distance, and was adherent to a great mass of the omentum which

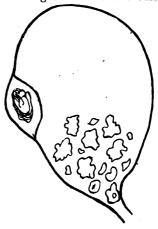

Fig. 9.

was spread out along its anterior border. On separating the adhesion I found the hepatic flexure of colon greatly thickened and fixed to the front of the right kidney by dense bands of adhesion. On sepa rating these, and drawing the colon downwards, I found strong bands fixing the pylorus and gallbladder (which was thick and shrivelled up) to the back of the transverse colon. These adhesions were now separated, and pushing the large intestines well in the abdomen I found the stomach enormously down distended with thickened walls an dovered by greatly engorged vessels. On exploring the gall-ducts I could discover no calculi, and as the gall-bladder was empty and much contracted I did not think it wise to do more than free it thoroughly and push it up into its proper position. Replacing the kidney in the loin, and seeing that the pylorus was thoroughly freed, I

closed the abdominal wound entirely.

In this case there was pain and distress for some time after operation; it was difficult to secure proper action of the bowels, but by the persistent administration of alkaline aperients, matters progressed favourably although slowly; and on May 5th she left for home in good health. This was evidently a case in which abscess in the gall-bladder had excited a localised peritonitis and then discharged into the intestine.

CASE XIII.—S. L., et. 52, came under my care on May 4th, 1998, complaining of epigastric pain, frequent fits of vomiting, rapid loss of flesh, and general usual, laid a short drainage tube and closed the incision. During the evening, after operation, she had several epileptic seizures, which yielded to proper her tongue was brown and dry, and she suffered

from persistent constipation. For some weeks paid had increased and extended to the right side under the ribs. This region was now tender on pressure and there was a fulness below the right costal arch, The temperature was high in the evening, up to 991; and was sub-normal in the morning, as low as 97.2. On examination under ether I found a fluctuating tumour which presented between the right costal cartilage and the umbilicus. Upon the history of the general condition I looked upon this as a case of suppuration of the gall-bladder. On May 11th I opened the abdomen by vertical incision in the right semilunar line, brought the gall-bladder to the surface. After breaking down adhesions and opening it I gave exit to twelve ounces of thin muco purulent material. After flushing out with warm boracic solution I explored the ducts and found them thickened but containing no stone. I fixed the gall-bladder in the ordinary way to the abdominal wall, and enclosed the incision at its lower part. For the first twenty four hours only thin sero-purulent fluid came away, then some bile appeared in the dressings, the discharge of bile continued until the 24th. On the 30th, the wound being quite healed, the patient left for home relieved of all her distressing symptoms.

CASE XIV. – E. O. came under my care on June 8th, 1898, having been in another hospital under medical treatment for six months. She was æt. 19, well developed and healthy looking. She comwell developed and healthy looking. She com-plained of intense pain under the right costal arch, occasional attacks of vomiting of clear bitter fluid. Constipation had been marked all through the case, and her strength had failed very much, owing to inability to take food regularly. There was great resonance under the right ribs and extending across the abdomen and upwards as high as the left nipple where the sound was tympanitic. Distension of the stomach with gas proved it to be enormously dilated, and on auscultation this gas passed through the pylorus with a continuous whistling sound showing that something interfered with the proper action of the valve. I could detect no tumour in the hypochondrium, but believing that the trouble in this case was the result of adhesions succeeding either gastric ulcer or gall-bladder, I carried out a laparotomy on June 20th, the incision being in the right semi-lunar line. The large and small intestine were so twisted up and adherent on the right side that I found great difficulty in separating them. On pushing the small intestine downwards, and excising a large mass of greatly thickened omentum, I was enabled to free the colon from adhesions deep down in the fissure of the gall-bladder. The withdrawal of this portion of the intestine enabled me to see the cause of the intense pain. In this case the pylorus was thickened, exceeding vascular, and there were numerous adhesions fixing it, and the beginning of the duodenum to the lower aspect of the gall-bladder which was empty, grey in colour, and small in size, but very thick walled. After freeing the pylorus thoroughly, I closed the abdominal wound. On the eighth day the wound had healed completely, and from the time of the operation no vomiting occurred. There was still some pain complained of in the right side, but after a fortnight this completely disappeared, and then mild aperients were effectual. This patient made satisfactory progress, and the trouble which had rendered her miserable for several years occasioned her no further uneasiness.

(To be continued.)

Mr. MITCHELL BANKS, of Liverpool, opened last week a new operating theatre in the West Derby Union Infirmary.

Dienna Clinical Lectures.

PSEUDOTETANUS.

By Prof. ESCHERICH,

Graz

Gentlemen,—I present to you a case of considerable interest, illu-trating in a forcible manner, a series of papers which I contributed some time ago to the Fren h medical press, under the title "Traité des Maladies de l'Enfance." In these essays I endeavoured to prove from cases coming directly under my own observation, that there are many spurious forms of traumatic tetanus which I ventured to designate "Pseudotetanus." a form that is neither tetanus or tetanic, but probably more nearly allied to the former than the latter. The principal features of the disease are the tonic intermittent contractions of the trunk muscles leaving the arms comparatively free, differing in this respect from tetany. The following case will better illustrate my remarks than a lengthy discourse on abstract principles.

on abstract principles.

Sanetti, S., æt. 5, with no hereditary weakness in the family history, had had typhoid fever last year from which he had quite recovered. On July 10th, 1898, the mother observed the boy had a stiff neck, of which, however, little notice was taken that day. Next day this stiff or cramped condition extended down the back to the lower limbs. Vomiting of brown-coloured matter accompanied these phenomena. On the third day the jaws became fixed, which led to his being

brought to hospital.

He was admitted on July 12, 1898. He was well nourished and healthy looking, except for the characteristic phenomena of traumatic tetanus. The boy lay in bed with all the muscles of the neck, back and legs perfectly tense, giving him the appearance of a statue. The muscles of the face were stiff, the teeth tightly locked, and the lower extremities the feet being in the pede-equino position. The arms, however, were under voluntary control, though the movements were slow and limited. At first these tonic stiff contractions were continuous, but later on the attacks were separated by intervals of varying duration, of which advantage was taken to feed the patient,

On the recurrence of a paroxysm an unusual phenomenon occurred which was photographed at the time, and is now reproduced in the accompanying

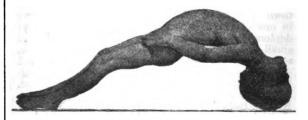

illustration. Whether this was due to spontaneous action or psychical irritation extending along the spinal muscles cannot yet be determined, but it was observed at the time that the features of the face were drawn or contracted as when it is exposed to a strong blinding sunlight. The head was drawn back, the spine curved, with the centre of curve posteriorly, till the crown of the head and point of the toes supported the whole body making the typical arc en cercle of hysteria. In this condition the upper part of the arm was pressed against the body, while the lower part was flexed or extended, sometimes alternately, while no tetanic symptoms were observed in the fingers. The muscles

of the entire body were as hard as marble, and stood out under the skin as firm ridges, the cutaneous surface meanwhile being covered with a cold clammy perspiration. These attacks ranged in duration from a few minutes to hours at a time, while the diaphragm would become so rigid as to endanger life from a similar condition existing in the other respiratory muscles. As might be expected, the breathing was irregular, ceasing either with inspiration or expiraration, but at no time were there laryngo-spasmodic sounds to be heard.

During the height of a paroxysm the child would become cyanotic, the lips and eyelids having a reddish blue colour, the eyes projecting, as if under the influence of carbonic acid narcosis. These attacks continued with more or less intermission from

July 14th to 24th.

The patient preferred to lie on his side or in a prone position which he seemed to think relieved his sufferings. During the whole of this period he had little or no sleep from the frequency of the attacks, while food and fluids had to be introduced into the stomach by means of a tube. The physical exertion he underwent really demanded a larger supply than in ordinary health.

On July 24th the contractions and attacks subsided so much that he could be fed with a spoon. On August 1st the greater part of the trunk was relaxed though the feet were still stiff. Slight attacks continued off and on till August 5th, when the patient seemed for the first time to be "himself again"

On August 20th, the patient could stand without assistance, but with the legs wide apart; movements in the arch of the foot being now possible. On the 24th he was discharged from the hospital apparently

healthy and well.

During the whole time of these attacks there was no fever and no disturbance of the vegetative functions; the sensorium was perfectly clear though the patient articulated speech with great difficulty and in a brief, jerky manner. Occasionally spas.nodic contractions were observed of the muscles of deglutition, but these were not constant. The facial phenomena could not be tested on account of the rigidity, neither could Trousseau's symptoms be elicited. The galvanic stimulus showed no altered condition of reaction either during chloroform narcosis, or in the interval of rest. No exalted state was detected by this means, but with mechanical stimuli the result was different. If the hand were firmly rubbed along the muscles of the arm an idiomuscular wave was immediately observed. The skin and tendon reflex were decidedly increased. During the severest attacks he complained very little of pain, except on several occasions in the neck.

Treatment.—This consisted mainly in tentative measures. Antispasmine in doses of 0.3 grms. was given without any perceptible benefit. After this bromide of potassium was administered in doses amounting to 4 and 5 grms. per day, i.e., from 60 to 80 grs,; this acted as a sedative, but did not check the attacks. In severe attacks chloral hydrate enemata proved beneficial but their effect was very evanescent, It may safely be asserted that medication had little

or no effect on the disease.

The connection between tetanus and tetani may be distinguished in this case by the absence of hyperexcitability to the galvanic current, and the absence of the pathognomonic phenomenon of Trousseau. On the other hand the reaction to mechanical stimulus, as well as the tendon reflex, was decidedly increased. The wide distribution of the spasms with lock-jaw, forcibly reminded one of traumatic tetanus, though the etiology was decidedly against this assumption.

On referring to my former records I find that this case, in common with the others, was associated with severe phenomena and a favourable result, and oc-

curred, like all the others, in the hottest season of

the year.

We cannot fairly estimate the frequency of occurrence of these cases, because so few of them have been recorded in the whole range of pediatric literature, yet I am inclined to believe that in milder form they are not very infrequent, though it is probably rare to meet with cases as well marked as

the above.

The Harbeian Tectures, 1898.

ON DISEASE AND ITS TREATMENT

PROFESSION OF MEDICINE

IN THE

YEAR 1899. (a)

By WM. EWART, M.D., F.R.C.P., Senior Physician to St. George's Hospital, and Joint Lecturer on Medicine to the Medical School; Senior Physician to the

Belgrave Hospital for Children.

LECTUBE III.—EDUCATION AND MEDICAL
PRACTICE.—(Concluded.)

THE ACADEMICAL AND THE UTILITARIAN IDEA.

The present system might be regarded as "academical" to a fault. The subjects are dealt with, as it were, in compartments. The pupil is taken through each of them from its beginning to its end. But often he might, perhaps, have done more for himself had he attempted less.

Too often, also, the teaching of valuable elementary subjects is practically divorced from their uses; and when the time comes when the chemical, the physiological, and the biological learning and methods might have been of practical value they have been forgotten. This would seem to suggest the desirability of associating, though not at too early a date, a medical purpose with the teaching of anatomy, physiology, biology, and chemistry, and to render their applications more clinical. Method, which represents the academical idea, is essential. Any of the sciences well learnt, but particularly anatomy and physiology, would serve this educational need. But the utilitarian or professional idea looks to those few great principles and facts without which no physician or surgeon ought to trust himself to work, as those upon which the main stress ought to be thrown in the teaching of the sciences. With these at his command, the pupil might progress by imperceptible degrees to a higher level of scientific and clinical efficiency, and the acme of his scientific training would be the study of practical pharmacology, which combines all the other clinical sciences. We do not notice any progression of this sort in our present system. Whilst elementary physiological matters are imperfectly grasped, some of the most difficult probl-ms, those which tax the expert, are made the study of the beginner. There is much to be said in favour of reserving these higher subjects as a reward for the veteran student.

The younger student's practical work in laboratories might with advantage be concentrated upon those methods which are of practical use, further knowledge being added upon a firm foundation of facts previously known. Thus, whilst avoiding the risk of a premature entry into the wards it might be useful to shift a great deal of the practical physiological work from the physiological to the clinical laboratory.

Work performed there in connection with the examination of the urine, of the blood, of the physical conditions of the normal organs, the study of the heart sounds independently of murmurs, of the respiratory sounds

independently of murmurs, of the respiratory sounds when uncomplicated by disease, of the position of viscera as recognised by palpation and auscultation, would never be regarded as wasted either by the student or later on

(a) Lecture delivered before the Harveian Society of London Dec. 15th, 1898.

by the practitioner, and would be useful additions to the

by the practicolar, and would be useful additions to the practical work of physiology.

Clinical laboratories in connection with teaching hospitals are a great need for students and for research Whilst in this country most philanthropists have made it their ideal to supply a sufficient number of beds and have overlooked the real pauper in the hospital-science -and the real need, that of a knowledge how to cure the diseases which are put into those beds, a much clearer view of things has long prevailed on the other side of the ocean. Practical sense has made it obvious that the object of hospital treatment is not euthanasia, but recovery, the secret of which cannot be learnt without the means of study. When this need is more widely understood among us generosity will soon flow in this neglected channel.

CLINICAL MEDICINE.

The cry from the obstetric side is, "Give us more time to train the clinical pupil in the most responsible and important part of his future practice"—a justifiable demand, but how can it be granted when clinical medicine itself is starved? Nominally three years are provided for clinical training. But too often after upwards of two years absorbed in preliminary studies, these subjects are forgotten, and may have to be learnt again at the expense of time properly belonging to clinical work.

The elementary clinical work seems to be too long delayed. After much time devoted to pure science and to examinations the pupil suddenly enters the wards unprepared. To him all clinical things are new. He is yet unfitted to utilise the advantages of a clinical clerkship which too often is conferred upon him at this stage. General elementary clinical practice is what he needs, and this he would quickly gain in the wards by contact with others of greater experience whilst completing his knowledge previously acquired in the practical work of physiology and chemistry, until he became able to take up with full profit the privileges of a clinical clerk, and study disease and its treatment in association with the physician, whose functions do not include the teaching of elementary methods. For lack of this, the most important part of his advantages as a clerk are often lost to him, and this accounts for the unfinished clinical condition in which so many have entered upon practice.

Medical Education. - Medical education would gain much in being made continuous by blending the clinical idea from a relatively early date with the scientific studies, and by keeping up a progression in the higher studies of anatomy and physiology. The student would find interest and meaning in each laboratory method, because shown to be connected with some clinical point, and his clinical anatomy and clinical physiology would remain his valued and lasting possessions.

Clinical Anatomy.—Anatomy, the "mathematics of medicine," will never cease to be indispensable and paramount among preliminary subjects, a fitting introduction to the most laborious profession. No part of anatomy is superfluous; but we cannot forget that entire subjects are being thrown overboard. Some parts of anatomy are of supreme importance throughout professional life, and the final examinations wisely require a knowledge both of surgical and of medical anatomy. But the average student has to learn these parts of the subject twice, because meanwhile he has been allowed to forget them. If this is the upshot, too much time has been claimed by anatomy at the beginning. The first year might suffice for undivided attention to the foundations of anatomy, whilst further instalments might be added by degrees and with a practical bearing. A study of the relations of parts might thus coincide with the teaching of operative surgery, and medical anatomy with that of practical medicine and of clinical work.

The long anatomical curriculum ought to lead as a net result to an accurate knowledge of those parts of the body with which we shall be professionally concerned. If the rest is to be finally forgotten, might not its teaching be compressed?

For the higher examinations, a late application to anatomy has always been necessary, and this shows that the suggestions thrown out are not absolutely unpractical.

Clinical Physiology.—Similar considerations apply to what I may term "clinical physiology." In physiology we use too little our great opportunities of studying man. What might not Harvey have accomplished had he been armed with our present instruments and methods of investigation? What should we think of a practical course on the circulation which did not include listening with the stethoscope to the heart sounds and learning accurately where they are to be listened for?
Or shall we deal practically with splanchnology, and not make ourselves familiar by palpation and by percussion with the position of the various organs?

All this is the physiology which is essential; not abstruse, not difficult nor repellant; and these physiological observations, though so important and indispensable, are of a purely elementary nature. They might afford an easy rise to the higher, truly difficult physiological inquiries for which many a young student is at first totally unprepared, and remains to the last unappreciative, whilst the living body appeals to every intelligent youth. The advantages of such a system would be great and would tell at both ends. Early in his career the student would be awatened to a professional interest in studies which would henceforth assume for him in all their theoretical details a practical purpose. The gain at the other end would be incalculable. Instead of his helplessness in approaching the bedside, the novelty of the situation and its strangeness would have long been removed. He would feel the confidence of an observer, and might proceed to truly clinical studies of disease instead of wasting the clinical opportunity upon mere instrumental practice at the wrong time.

CENTRALISATION AND THE ONE-PORTAL SYSTEM.

The continued agitation for reform has been a prominent feature of recent years. In this the profession has shown its earnestness in the cause of progress. Centralisation is the question of the day; it lies behind most of our present problems, and in particular of those relating to University teaching, to the multiplicity of schools, to the variety of examining bodies, and to the relative value of the titles conferred by examination. But we may be well advised in not departing more than is unavoidable from the opposite system, perhaps less perfect in its form, but more fertilising, a system to which we owe that which we are. Let us beware of sacrificing the vitality and spirit of our great professional bodies to the doubtful advantage of a monotonous uniformity.

The one-portal system was some years ago even more urgently needed than it now is. Further improvement is necessary, but it is a question whether any radical change is indispensable. All that is practically wanted might be attained by all the corporations raising the standard of their examinations to a uniform level which would obviate any downward competition between them, and at the same time would exclude from the profession, if possible at the entrance examination, those who are not thoroughly equal to its responsibilities, so that none but the fittest could get their names on to the Medical Register.

THE PLACE OF THE PROFESSION, ITS SERVICES AND ITS REWARDS.

The Service to the Individual and to the State.- I have dwelt upon the altruism of the profession in its constant war against disease. The character of the personal service rendered by its individual members is well known to us. It is often true, and not alone on the field of battle, that life itself is offered in the hope of saving life. There is little wonder that our profession should supply a shorter average of life than any other. Alone, the med cal men is never allowed to be ill; and he is singular in continuing to work while ill. No other profession claims that its labour shall be carried on at night and on holidays, and to this must be added the constant exposure to infection and to other risks.

But it is not sufficiently realised that the work done

by the profession in saving the lives of individuals and in checking the spread of disease is a direct service and a direct gain to the State Has its practical value been fully recognised? We enjoy, it is true, and are thankful for the favour and the protection of the State. But

beyond charters and privileges such as are granted to great commercial associations working for their own profit and only indirectly for the good of others, little has been bestowed upon us. On the basis of this service we might as a profession have been in a position to treat with the State. This was the custom with the ancient guilds. No such bargain has ever been submitted from our side. Men of medicine have parted with their "mystery" without even thinking of an equivalent, which has not been proposed from the other side in the shape of any practical recognition.

Thus whilst other professions act on the principle do ut des, the great fruits of medical science which prosper our days of peace and ensure the success of our wars are a free gift to the State. And that profession which alone shares with the Church the direct care for the welfare of

the community has little share in its honours.

The Deserts of the Profession .- Yet, having regard to the value which the individual sets upon his own life, to the actual value which the lives saved represent to the State, and to the untold boon conferred upon suffering humanity, it is difficult to see what recognition could be adequate. In a younger world, with such a record, healers of the sick would have walked as gods among men.

From the individual, the medical attendant receives an honorarium only, in acknowledgment of a debt which cannot be entirely paid. By the State this acknowledg-ment of debt is hardly made and the honorarium is scantily bestowed, though statesmen admit that without a healthy population there can be no national greatness.

The Place of Medicine among Professions .- Precedence between professions and their social status are regulated by custom, and there is no desire among us to disturb these ancient traditions. It may be said of all professions that they have risen in dignity. In the case of medicine, the rise in worth as estimated in vastly increased knowledge, in usefulness as judged from the amount of human life saved, and in influence as regards the practical reforms administered by the State under our guidance, has been out of all proportion to any position which it has ever held.

The end of the last century witnessed a revolution in France which brought to the front tumultuously the social layers by whom the chief work of the world had been carried on without recognition. Less hastily, but with unfaltering step medicine has been marching towards its proper place in the front rank of the profession. What is the medical profession in the State? Nothing. What should it be? The chief and most important influence; for it was truly said, "Sanitas Sanitatum et omnia Sanitas."

The Reward: its Deeds and its Dignity.—The power silently wielded by our profession is ever increasing, and must give it importance and ultimately a foremost position. For the present its reward lies in the consciousness of this fact, imperfectly realised by our fellow men; and also in its dignity, in its intellectual work, and in a knowledge that its ministrations are indispensable as well as beneficent. In this isolation and this consciousness of power there is a superiority.

The profession is a self-made aristocracy of usefulness, whose distinction is not exclusiveness but the widest sympathy, whose strength is not privilege, but prodigal se'fsacrifice. Let the estimate placed upon it by its members never fall beneath its great aims and achievements. Our part as its representatives is one of increasing loyalty and self-dignity. This duty lies before each of us, and its fruits are within our own grasp, as may be seen by the success of combined action whenever it has been attempted.

In addition to Pandora's legacy to our race, there is for our profession a large inheritance of charity as well as of faith in the progress of humanity, and in its own destinies. These things that we see and know cannot much longer escape the notice of the people and of their

leaders.

SIR JAMES REID, Bart., K.C.B., has been appointed by the Prince of Wales Physician in Ordinary to His Royal Highness, in succession to the late Sir William Jenner.

Clinical Records.

WESTMINSTER HOSPITAL.

Enteric Fever without Symptoms.

Dr. Murrell called attention to a case of enteric fever in which there were practically none of the ordinary symptoms of that disease. The patient, æt. 24, was admitted on the sixth day of illness, and complained of inothing but slight headache, a little cough, and some dryness of the throat. The temperature at 4 p.m. on admission was 101.8, and at 12 p.m. 102.4. On the following day the lowest temperature, at 8 a.m., was 100.2, and the highest, at 8 p.m., 102.4. On the next day, the 8th of the illness, the temperature at 8 a m. was 98°0, and at 8 p.m., 102°6. On the 9th day the highest temperature was 101°4. On the 10th day it was 97°8 in the morning, and 101°6 in the evening. From that day until the 15th day the temperature was always normal in the morning, and rose to 101 deg. in the evening. After the 15th day the temperature was never above

100 deg., and from the 21st day onwards was normal.

During the whole of the 42 days the patient was under constant observation he looked perfectly well. He was bright and cheerful, and complained of nothing but the inconvenience of being kept on a diet of milk and

beef-tea.

His bowels were regular, and there was not a single motion indicative of typhoid.

No spots were seen either on the abdomen, or on any

other part of the body.

There was no fulness in the abdomen, and no gurgling in the iliac fossa

There were no abnormal signs in the chest.

The only definite sign was a slight enlargement of the spleen.

Widal's reaction was obtained on the 14th day.

It was thought that the fever might be tuberculous in origin. Against this were the facts that (1) there were no abnormal signs in the chest, and (2) that repeated examination of the expectoration failed to detect tubercle bacilli.

The patient was hoarse, and it was suggested that there might be tuberculous disease of the larynx. The cords were examined, but no indication of tubercle could be detected. The hoarseness was probably the result of his occupation—a street-hawker. It was suggested that the fever might be syphilitic in origin, but its duration was against it, and there was no history or indication of the presence of the disease. The only conclusion that could be arrived at was that it was a case of enteric fever of so mild a description that there were no symptoms and no signs, with the exception of (1) the temperature; (2) the enlargement of the spleen, and (3) the typhoid reaction.

Cases of ambulatory typhoid are well-known, but many of these ultimately run a very unfavourable course. Cases of apyrexial typhoid have been recorded by Dreschfeld, but in most of these there were other well-marked symptoms, such as diarrhoea and hemorrhage from the bowels. Cases of typhoid in which so few symptoms present themselves from first to last are rare. or at all events, are rarely recorded.

SIR W. McCORMAC, Bart., K.C. V.O., Sir William Turner, F.R.S., Dr. Lauder Brunton, and Dr. W. McEwen have been elected honorary members of the St. Petersburg Academy of Medicine.

Mr. T. T. Bucknill, Q.C., who has been appointed a judge of the High Court, in succession to Lord Hawkins. is the second son of the late Sir J. C. Bucknill, M.D., F.R.S., the pioneer of the volunteer movement. The new judge was born in 1845, and is at present the Member of Parliament for the Epsom division of Surrey, in the Conservative interest.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.
MEETING HELD WEDNESDAY, JANUARY 4TH, 1899.

The President, Dr. Cullingworth, in the Chair.

SEVEN MONTHS' EXTRA-UTERINE FŒTUS REMOVED BY VAGINAL INCISION.

Dr. Donald, of Manchester, related the case of a patient, et. 33, admitted July 20th, 1898. Married. Since about a year she had been regular until January 30th. She had a slight discharge in February, and in March there was bleeding for three weeks. The abdomen began to swell and the breasts enlarged, and lastly the fœtal movements became perceptible. On admission there was marked abdominal tenderness, the patient was very thin and anæmic, and there was an abdominal tumour reaching four inches above the umbilicus, firm below but elsewhere somewhat indefinite in outline. A loud soufle was audible, but the fetal heart could not be heard. By vaginal examination the posterior fornix was found to be occupied by a hard mass, evidently the feetal These facts were made out while she was resting in the hospital for a fortnight. He experienced some diffi-culty in deciding what would be the best course to pursue, the patient suffering considerably from pressure symptoms. Before deciding to remove the child through a vaginal incision, he thought it best to make an abdominal incision in order to ascertain the whereabouts of the placenta. He operated on August 18th, and immediately on opening the abdomen he came down upon a large bluish mass, which was unquestionably the placenta, and this he took every care not to disturb. He then intro-duced a large sterilised pad into the abdominal wound, and made an incision through the posterior fornix with scissors. He came upon the feetal head, which it was evident could not be directly removed without considerable damage to the soft parts, so he perforated and crushed it, after which the feetus was removed. The cavity lett was plugged with gauze. There was considerable hemorrhage from one corner, which was considerable hemorrhage from the cavity and considerable hemorrhage from the cavity removed without considerable hemorrhage from the cavity removed. trolled by large pressure forceps. The patient made an uninterrupted recovery, except that on the removal of the gauze alarming hæmorrhage occurred, which was arrested by the reposition of the plug. Sloughing and suppuration of the placenta did not take place for several weeks, and then some weeks elapsed before it had all come away. At no time, however, did her condition give rise to any anxiety. She was discharged well on November 12th. He commented on the unusual position of the fœtus. The peritoneal covering of the gestation sac was continuous below with the parietal layer of peritoneum, in fact its relations were exactly those of an intra ligamentous cyst. It was evident that pregnancy had developed in the folds of the broad ligament, and that in all probability rupture had occurred at the time when she had the hæmorrhage lasting three weeks in March The objections to the vaginal method were that the operator was liable to tear through the placenta or cut into some of the large vessels; it was also asserted that the risk of sepsis was greater than by the abdominal method. The first of these objections was the only serious one, and for this reason he thought it was advisable to make out the situation of the placenta before operating per vaginam, even if in order to do so an abdominal incision was necessary. When this point had been cleared up he thought that the vaginal method was a comparatively easy and safe way of removing the fœtus.

Mr. Alban Doran agreed on the importance of ascertaining beforehand the site of implantation of the placenta, which indeed was the main point of the paper. Dr. Galabin thought the vaginal incision offered cer-

Dr. Galabin thought the vaginal incision offered certain advantages in comparison with the abdominal method. By the latter method it was generally necessary to stitch the gestation sac to the edges of the abdominal wound, thereby greatly prolonging convalescence. This, moreover, left a weak point in the abdominal wall. These objections did not apply to the vaginal method, and if a sinus remained for a time it was not productive of any great inconvenience.

The PRESIDENT observed that with regard to the incision through the roof of the vagina the author might claim to be somewhat of a pioneer in this country. The author was, he believed, the first to remove early ectopic gestations through the vaginal roof. He recalled a case of peculiar interest which the author had placed on record, the patient being a danseuse who had professional reasons for wishing to avoid a scar on the abdomen and the sac was therefore opened through the vagina with success. He asked what the author supposed was the source of the hemorrhage when the tampon was removed.

source of the hæmorrhage when the tampon was removed.

Dr. Donald, in reply, pointed out that if one had attempted the operation in this instance through the abdomen the operator could hardly have avoided disturbing the placenta with disastrous results. Operating as he had done through the vagina the operation was practically extra-uterine. The hæmorrhage appeared to come from the edges of the sac.

VULVAL DISCHARGES IN CHILDREN.

Dr. Drummond Robinson read a paper based on a series of 54 cases of vulval discharges in children with clinical and bacteriological observations thereon. He described the gonococcus and the means of distinguishing it from other intra-cellular diplococci. He had been enabled to discover this organism in 41 out of the 54 cases. The affection was often markedly transmissible and thus epidemics occurred, the infection being passed on from child to child either by manipulations or possibly by the use of the same chamber utensils. The affection was most commonly observed under the age of five, and 39 of the 54 of the patients observed by him were under that age, only four being over ten. It varied very much in respect of duration, and painful micturition was a common symptom. Vaginitis, on the other hand, was uncommon. He pointed out that he had had to rely mainly on the microscopic appearances as the gonococcus was very sensitive to changes of temperature, and unless special precautions were taken its vitality would be destroyed before it could be cultivated. The culture, however, had been successfully carried out by several foreign observers.

Dr. HANDFIELD JONES said he had seen a large number of these cases of inflammatory affections of the genitals in children. The inflammation was usually limited to the vulva or to the neighbourhood of the hymen, and in but a small proportion did it invade the vagina. He observed that if gonorrhea were the source of the trouble one would expect. as in the adult, to find a rapid extension of the disease along the whole length of the genital tract, causing salpingitis, &c He had remarked that a large proportion of the children affected in this way were delicate, and it was met with seldom in strong, healthy children, as for example, in country children. Although the disease was common, involvement of the inguinal glands was very rare, whereas, in ordinary gonorrhœa these glands were commonly involved. Moreover, it seemed that in a large majority of the cases very simple hygienic measures effected a cure in a short time, while in typical gonorrheal infection the cure was long and difficult. He had seen a few cases of undoubted gonorrheal infection where men had attempted to violate children. The contrast between the acute course of the one and the mild course of the other was very marked. On the whole he thought that in this connection nothing was more deceptive than "facts."

Dr. Boxall suggested that in view of the large proportion of these cases in which a diplococcus was found it was strange that so few instances of the conjunctiva being affected had been noted, especially as with children when there was pruritus such conveyance of infection was exceedingly likely. He thought that the clinical evidence was not much in favour of these cases being gonorrheal.

Dr. A. Routh commented upon the comparative rarity of vaginitis in these cases, and when present he suggested that in some cases it was not improbably the result of infection conveyed by the finger of an incautious examiner.

The President observed that even in adults vaginitis was not common in association with gonorrhea indeed, it was quite exceptional. Gonorrhea usually attacked

the vulva and the cervix uteri, the vaginal mucous membrane not lending itself apparently to infections. He had not remarked any particular tendency of the inflammation to attack the urethra.

Dr. Robinson, in reply, agreed that vaginitis was a very rare complication of gonorrhea in the adult female, but he could not agree that the urethra was seldom attacked. His experience was that this was usually the case, the cervix being attacked next in point of frequency,

then the vulvo-vaginal glands, and lastly the vagina.

The President pointed out that the difference might be accounted for by the fact that the statistics upon which the author relied were based on the examination of prostitutes, and not upon the ordinary run of out-

patients.

Dr. Robinson added that in his own experience the subjects had not been principally delicate or unhealthy children. One could not be absolutely certain if one relied exclusively upon the microscope, but there were difficulties in the way of culture tests. Nevertheless, when one found an intracellular diplococcus in a discharge from the genital tract the chances were greatly in favour of a gonorrheeal origin Personally he thought the evidence was in favour of a gonorrheal origin, and the cases showed that the disease in children differed in many respects from the disease as it occurred in adults

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF SURGERY.

MEETING HELD FRIDAY, DECEMBER 9TH, 1898.

The President, Mr. R. L. Swan, in the Chair.

ADJOURNED DISCUSSION ON SIR THORNLEY STOKER'S PAPER ON "COXA VARA."

THE PRESIDENT said he was doubtful whether as a disease, or as a special disease, it was worthy of the great argumentative accuracy and talent that had been spent upon it. Sir Thornley Stoker had said that they might couple these cases of osteo-malacia occurring in adults with coxa vara - a disease of childhood and adolescence. He himself had never seen osteo-malacia, because his experience of any deformed condition of the femur had been an accentuation of the natural convexity of the femur from the habit of leaning on the left leg. He did not think that any practical surgeon would mis-take morbus coxe for coxa vara in infants or children, as coxa vara is a symptom of rachitis, and there would be other conditions, he thought, to mark the difference.

Mr. Lentaigne questioned whether some of the cases

of so-called morbus coxe in early stages, which had been successfully operated on, were not merely cases of coxa He had recently seen a case of coza vara, which he thought might easily have been mistaken for early

hip-joint disease.

Mr. T. MYLES did not agree that the condition of coxa vara was easily diagnosed from morbus coxe, for until the condition was described the mistake must have occurred a great many times. As yet the condition had not been accurately defined. Apparently it is applied to all cases in which there is a change in the normal angle of the femur. If caused by osteo-malacia or rickets he thought that it could not be called a separate disease. He thought it extraordinarily like morbus coxe in the early stage.

Mr. Croly said that he failed to see why coxa vara could not be diagnosed from morbus coxe. He had seen many dozens of cases of morbus caxe treated, and could not say that coxa vara had ever attracted his attention. What proof was there that cases which had been treated as morbus coxe were really coxa vara? He did not believe that such had happened. He believed that cases which he had treated as morbus coxe were morbus coxe.

Sir W. THOMSON said that the condition had undoubtedly been overlooked, and was different from morbus coxæ. He did not see why—although he admitted that there are certain cases in which there is plenty of evidence of this general condition—one could claim rickets as a cause when the condition is confined

to the neck of the femur, and there is no evidence whatever in the rest of the skeleton of any rachitic condition. But he was satisfied that any condition in the neck of the femur which would lead to softening, whether inflammatory or pre-tuberculous, is sufficient to allow straightening of the neck or the reduction of the angle.

Sir THORNLEY STOKER, in reply, said that the subject was a new one, and, of course, there was room for difference of opinion. Those who had differed from him would, he thought, find their contentions answered if

they read his paper.

THE OPERATIVE TREATMENT OF HERNIA.

Mr. M'ARDLE brought forward the subject of the radical cure of hernia, bising his communication on the results in 342 cases. The ages of the patients ranged from 8 months to 85 years. Of this number but one died, and that was an instance of umbilical hernia in a man of 65, very stout, and with weak heart and atheromatous arteries. Mr. M'Ardle advocated:—1. Free opening up of the inguinal canal, so as to have complete control of the internal ring. 2. Interrupted suture of the internal oblique conjoined tendon to Poupart's ligament, leaving the cord in its normal position. The sac might be ligatured, sutured, or drawn through the external oblique after Kocher's method, but the fundus should be removed, as it could serve no useful purpose however placed. It was a grave mistake in Kocher's method to bring the sac down, and cause it to act as a wedge in the anterior part of the inguinal canal, and in all these cases where the sac was puckered, twisted, or invaginated, its retention was a danger, as proved by many instances of necrosis of the sac, delay of healing, and even of death. Mr. M'Ardle's belief is that the method of dealing with the sac is of no moment so long as we exclude the dangerous and ineffective methods mentioned. A Bantock's ligature placed on the neck close to the internal ring brings the peri-toneum to its normal condition. Mr. M'Ardle stated his conclusions as follows:-1. Without opening up inguinal canal no complete operation can be performed. 2. It is a matter of little importance what you do with the hernial sac; it has no bearing on the case; a new sac forms with the greatest readiness, if at any point the mid-stratum of the abdominal wall is defective. 3. There is no evidence in favour of opposing the arrangements of Nature by displacing the cord. 4. To properly reconstruct the canal, the internal oblique and conjoined tendon should be brought down to Poupart's ligament, not more by the case of the arternal oblique. not merely to the edge of the external oblique. 5. The complete overlapping of the pillars of the external ring forms a firm basis of support for the healing of the underlying conjoined tendon.

Mr. CROLY believed that closure of the internal ring is the most important part of the operation for the radical cure of hernia. Slitting up the inguinal canal and suturing it without closing the internal ring is not sufficient, and would be followed by return of the hernia. He himself liked the displacement method of Kocher best, and his experience of that operation was that the

method was excellent.

Mr. T. Myles said that it had to be decided which of two fundamental principles one proposed to adopt in performing the radical cure of hernia—whether it was intended to rely merely on reposition of the sac and super-imposition of an obstacle at the commencement of the inguinal canal, or whether it was intended to ignore the sac and rely on an attempt to restore a condition analogous to that of healthy persons. He believed that every case of acquired hernia has a congenital basis as its origin. The force which prevents the descent of a hernia, by the exercise of that same force occludes the channel through which the hernia would descend—in other words, the canal is valvular. The greater the pressure within the abdominal cavity in a properly formed individual the more forcibly will the posterior wall be applied to the anterior wall of the canal. In every case of hernia the distance between the external and internal rings is diminished. The internal ring, in cases of hernia, is always larger than normal owing to defect of development of the conjoined tendon. If this theory is correct, then any attempt to prevent descent of hernia by manipulation of the sac would end in failure. He failed to see exactly what Mr. Croly and Mr. Ball,

in a recent article, meant by closure of the internal ring, and the approximation of the superficial and deep structures of the canal. The internal ring, as it existed in cases of inguinal hernia, really had only one border—viz., the edge of the conjoined tendon. So far as the mere dealing with the sac is concerned, he condemned Mr. Ball's method. Twisting of the sac in Mr. Ball's method produced a vortex and a smooth lining membrane over it. He thought that necrosis of the sac could only occur when an enormous redundant mass of tissue is left below. In the first place, a tissue is left which is bound to die; and in the second place, a hindrance to the second step of the operation is left. He agreed with Mr. M'Ardle in the first part of his operation, except that he did not make the incision so long. He did not like Halsted's operation. His own opinion was that a radical cure could be made in a man who has an approximation to a normal inguinal canal.

Mr. Ball did not believe a smooth surface of peritoneum could be obtained by any method in which a ligature is applied to the neck of the sac, no matter how high up it is put, and there will be always left a depression above the ligature through which a subsequent hernial sac can be produced. One should aim at the obliteration of any depression at the point where the neck of the sac originated from the peritoneum, and also at the efficient closure of the inguinal canal. He thought it improbable that any suture which brings the anterior pillars of the ring together will cause any union between them. But the fascia derived from the fascia transversalis, which comes down, as a rule, on the hernial sac, s a vital structure, and any operation dealing with a hernial sac must tear the sac away from this tube of fascia, and suturing of the inguinal canal must occlude this long canal of fascia. He was now in the habit of doing a slight modification of his operation as originally published, which was suggested to him by Kocher's operation. After bringing down the sac, and twisting it till the sac and neck were sufficiently twisted to occlude the whole length, and to throw into folds the peritoneum surrounding the inguinal canal, a silk suture is passed up through the inguinal canal and brought out through the entire thickness of the abdominal wall, and out through the skin. The needle is threaded on the other end of the silk, and is passed up, and brought out through the skin at a point on the same level about an inch above the apex of the external abdominal ring. On dealing with that loop, what might be called the "bite" of the stump is caught, which is pulled up in the subperitoneal tissue at the back of all the abdominal muscles, and is fixed at a certain point by tying the suture over a little lead button, where it can remain for eight or ten days. If the fundus is of moderate size it will lie in the apex of the abdominal ring. In the further steps of the operation the fundus of the sac, together with the spermatic cord, is pressed backwards round the edge of the conjoined t-ndon towards the peritoneal cavity, and a curved needle, threaded with silk, is passed through all the lateral structures of the inguinal canal. By his method the sac was directed upwards to the point where it is fixed, and if that tends to dilate, it tends to dilate against the strong muscular abdominal wall, instead of against the weak inguinal canal.

Mr. Tobin urged that one ought to try to get a new union and smooth closure for the opening in the radical cure of hernia, and attempt to bring back the parts to a condition in which, if forces were applied, there would be no spot on which there would be a particular drag. He thought that a more even surface could be obtained by applying a ligature round the sac than by Mr. Ball's method.

Mr. M'ARDLE, in reply, said that he still believed the only way to cure hernia was to close the middle stratum of the abdominal wall. It was necessary to secure the neck of the hernial sac by all means, but that was not the one desideratum. Mr. Croly, he thought, had been mistaking the neck of the sac for the internal abdom nal ring. Ligature will not secure the ring, because there is nothing to ligature. It was to make the valvular condition of the wall more perfect that he carried out his operation. He emphasised the fact that not alone did the structures which he had mentioned join, but that the | Eccles.

external pillar united to the internal pillar. This he had proved by subsequent dissection for other things. Regarding the question of the fascia transversalis, in any operation the needle used to bring together the conjoined tendon, the transversalis, and the internal oblique take in the transversalis fascia, and also the subperitoneal fatty tissue. The similarity of Mr. Balls method to Cheyne's was very marked as described by himself. The question of the bladder is very important. The bladder might be pulled up without any peritoneum behind it, so that the muscular tissue of the bladder comes out behind the sac. It could not be detached, for if this were done it would be detached from its peritoneal covering above.
The Section then adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JANUARY 6TH, 1899.

Dr. S. D. CLIPPINGDALE, President, in the Chair.

Mr. Lake read a paper on the

TREATMENT OF LANEYNGEAL PHTHISIS.

based on a series of 160 cases. He did not enter into any discussion of methods of treatment he had not tested. Clinically the cases could be resolved into groups, each of which derived benefit from slight modifications of treatment.

He particularly dwelt upon the advantages of intra-tracheal injections in cases of superficial ulceration and slight swelling, but admitted of its uselessness alone in cases of greater severity.

The case was discussed by the President, and Messrs. McAdam Eccles, James, and Atkinson.

Mr. J. R. Lunn read a paper on

"TWO CASES OF DOUBLE OPTIC NEURITIS" ASSOCIATED WITH MASTOID DISEASE.

Case I. a boy, set. 11, complained of giddiness and severe pain in the right ear from which there was a little offensive discharge. He appeared to be quite deaf. Behind the right ear was a fluctuating swelling. In two days the patient became delirious and then maniacal, and the swelling behind the ear became larger. Under an anæsthetic a perforation of the membrana tympani was discovered. The mastoid cells were trephined and found to be full of offensive, cheesy material. The operation was necessarily extensive, and at the end of the excavation the pulsating lateral sinus could be seen. The patient made a good recovery and the optic neuritis soon cleared up.

Case II. a girl, at. 14, who had suffered from ear trouble since an attack of measles and scarlet fever when 7 years old. Behind the right ear was a fluctuating swelling, and from the meatus flowed an offensive discharge. Deafness was marked. The right membrana tympani was perforated, and both optic discs showed signs of optic neuritis. The right mastoid process was trephined, and much sclerosed bone had to be removed before the offensive caseous matter could be reached. The patient made a good recovery, and the optic neuritis soon disappeared.

The paper was discussed by the President, Mr. Lake, and Dr. Batten.

Dr. James Allan showed a specimen of hypertrophied prepuce. Dr. Allan also read a paper on "Twelve Cases of Tracheotomy for Laryngeal Diphtheria in Young Children, with Nine Recoveries." The details of the operation were discussed, and stress was laid on those points which the author considered important. It was shown by reference to a case that tracheotomy some-times gives the most brilliant results in apparently hope-less cases. The indications for the operation were dis-cussed, and the dictum "When in doubt operate at once" was quoted with approval.

The paper was discussed by the President, Dr. Gibbes, and Messrs. Lunn, Lloyd, Atkinson, and McAdam

BRADFORD MEDICO-CHIRURGICAL SOCIETY. MEETING HELD AT THE ROYAL INFIRMARY, DECEMBER 20TH, 1898.

The President, Dr. Berry, in the Chair.

Dr. Enrich gave a demonstration of microscopic sections from a series of ovarian tumours. He mentioned that the malignant or non-malignant character of a tumour could not be determined until operation; also that in the same tumour there could be demonstrated a change of type from innocent to malignant; and further, that in the ovary itself, although it may not apparently be involved in the tumour, yet malignant disease may be demonstrated microscopically.

Mr. Hall remarked that a tumour may exist for years without showing symptoms of malignancy, and advocated early removal of all tumours as soon as diagnosed.

Mr. Hall read a paper on the

OPERATIVE TREATMENT OF BREAST CANCER.

He expressed the opinion that there was a brighter future for the surgical treatment of breast cancer than for that of any other form of malignant disease, provided only that the disease was recognised early, and that a thoroughly radical operation were performed. He con-tended that the bad results of operation in the past were the result of imperfect removal, and pointed out how greatly the percentage of cure had increased since the introduction of the more extensive methods of operating. The aseptic treatment of wounds rendered it possible to undertake these operations without grave risk to life. The reader of the paper then gave a summary of the results of different surgeons from 1870 to 1898, and contrasted the 5 per cent. of cures obtained by Billroth in the earliest decade with the 50-60 per cent. obtained by Halsted, Watson, Cheyne, and others in the last few years. Billroth's cases, published in 1878, showed an immediate mortality of 24 per cent., while Halsted's series of 133 cases, between 1889 and 1898, recovered without any death from the operation. Bennett May recorded in 1897 78 cases without a death. Allusion was made to the researches of Heidenhain, Stiles, and others on the course of the lymphatics of the breast, and the conclusion was stated that no operation can be deemed satisfactory unless not only the breast and axillary glands are removed but also the lymphatic channels which run in the pectoral fascia. Halsted's operation was selected as fulfilling these requirements. A description of Halsted's operation was then given, and diagrams shown illustrating the steps of the procedure. It was stated that very little loss of function followed the operation, and that it was generally possible, owing to the large mass of tissue removed, to cover in the wound without undue tension on the skin. Mr. Hall said that in the older method of operating the pectoral muscle, after being stripped of its fascia, became much infiltrated with fibrous tissue, and consequently suffered considerable loss of function. The idea that the operation would be accompanied by an increased immediate mortality was negatived by the results of operators who have used it. Mr. Hall contended that by no other method could the contents of the axilla be so easily and safely removed in consequence of their being fully exposed to view and the possibility of employing scalpel and forceps instead of the finger. The question of operating on cases, which were too far advanced to hope for a cure, was then discussed. Operation as a palliative measure was advocated in all cases where there was a reasonable prospect of removing the whole growth, and in which the operation would not be exceedingly dangerous to life or leave a hopeless functional result.

Mr. Horbocks remarked that he thought in most cases the operation was unnecessarily severe, and thought that the pectoral fascia could be removed without removing the whole muscle. He said that the results of operation in cases of atrophic scirrhus should not be grouped with the results in rapidly growing cases, as the prognosis was so much more favourable, and consequently statistics of mixed cases were unreliable.

Mr. ALTHORPE said that the more favourable results of later years as compared with the results of earlier operations were in part due to improvement in operative technique, whereby the immediate mortality of operations was much reduced.

Dr. Berry asked if it was a fact that cases in which suppuration occurred were more likely to be followed by a cure than those in which primary healing followed.

Drs. Heine, Wood, Bell, and Arnold Evans also offered

Mr. Hall, in reply, expressed the opinion that it was not possible to remove the pectoral fascia completely while leaving the muscle behind. He said that possibly the apparently better results in cases which suppurated were due to the circumstance that the suppuration might be produced by a very extensive handling and bruising of the tissues consequent on an extensive operation.

Dr. J. H. Bell read notes of a case in which hæmatoporphyrin had appeared in the urine. The case was one of a nervous affection accompanied by insomnia, and sulphonal had been given to induce sleep. The sulphonal had been given in 10 grain doses, but the patient had continued the administration when no longer under medical advice.

France.

FROM OUR OWN CORRESPONDENT.

Paris, January 7th, 1899. TYPHOID FEVER.

A serious epidemic of typhoid fever is reported as existing among the troops at Cherbourg, especially affecting the Marines. The number of cases at present under treatment at the Naval Hospital exceeds 300. The infection is believed to be due to ingestion of water from the river La Divette, and instructions have been issued for precautions with the view to prevent the further spread of the epidemic.

THE FEVER SCARE AT NICE.

It is stated that the hotel proprietors of the South of France are suffering severely from the absence of the usual English and American winter visitors, and that the majority of the leading hotels are being carried on at a heavy pecuniary loss. The fever scare at Nice, I understand on good authority, arose thus: A certain rich newspaper proprietor, who shall be nameless, rented his Riviera headquarters from the Mayor of Nice, whose private property it was. On expiration of the lease heas landlord, doubled the rent, and refused to let it for less. Thereupon the former occupant removed to Monte Carlo, and threatened to have his revenge. Straightway there appeared letters in the Times and other leading English and American newspapers inaugurating the fever scare. It is obviously impossible to control the accuracy of this rumour, but countenance is lent to the assertion by the letters of Dr. Allan Sturge and other resident medical men utterly denying that there has been lately, or is, any fever in the Riviera. That there has been a mild attack of "Fashoda fever" cannot be gainsaid, but this national ferment has ceased; indeed, it may be affirmed that among the thinking portion of Frenchmen it never existed, and from recent personal knowledge I can testify that the Riviera was never so well drained or so well supplied with pure water as now, whilst the hotel accommodation is all that can be desired. I have thought it well to make these remarks in the interest of invalids and others seeking health who have been deterred from going to the Sunny South by newspaper correspondence which in any case is not above suspicion.

TREATMENT OF ARTERIO-SCLEROSIS.

M. Lancereau presented, at the meeting of the Académie de Médecine, a young woman with generalised induration of the skin, and a man suffering from chronic rheumatism, gout, and arterio-sclerosis. In the woman the skin of the face had lost its elasticity, was smooth, brilliant, and indurated, while the teguments of the neck and trunk were so thickened that the movements of the arms and the respiration were considerably impeded. Under the influence of iodo-thyrine, administered in progressive doses (ten to sixty grains a day), the patient improved rapidly. After four months of this treatment, the skin of the face recovered its normal aspect, that of the trunk and the neck became more elastic, and the movements of the arms great; facilitated, so that the woman, who for the last two years was incapable of any kind of work, could now use her needle without the slightest trouble.

In the second patient, the iodo-thyrine acted like a charm on the rheumatic pains and the osteophytes, while the arterial tension diminished, and the peripheric arteries lost their hardness and their sinuous appearance.

TUBERCULOSIS OF THE TESTICLE.

M. Reynier read a paper on a case of tuberculous disease of the testicle treated by castration and resection of a large portion of the vas deferens in a man, æt. 26. In order to be able to remove a sufficient length of the vas deferens, the operator had to incise the inguinal canal and turn aside the peritoneum. It should be remarked, the speaker said, that frequently in practising castration for tuberculous disease of the testicle the section of the vas deferens was not made high enough; persistent fistulæ were the result. In three cases he was obliged to resect a second time the canal Generally speaking, he believed that one should not hesitate to operate as completely as possible in the above affection, which was by no means benign, for in spite of the best general treatment it might infect the lungs if allowed to develop.

LUPUS (ERYTHEMATOUS).

A well-known professor recommends in the treatment of lupus (erythematous) applications of proof spirit. A young woman suffering from this affection was treated by cauterisation, but the patch always remained a bright red. Lotions of proof spirit were applied, and in a few weeks the malady disappeared completely. Of five other cases thus treated, four were chronic, the fifth acute. Three of the former were cured in a few weeks, but the fourth was only slightly improved as the patient had not been able to treat himself properly. However, it was in the acute case that the alcohol seemed to have acted particularly well. The lupus occupied almost the whole surface of the face and invaded the neck, down to the sternum. At the end of four weeks of the alcohol lotions no trace of the eruption was left, and had not returned up to the time of writing (six months).

The treatment consisted simply in passing over the parts a plug of cotton imbibed with proof spirit or, what was preferable, in a mixture of

Proof spirit
Sulphuric ether
Spirit of peppermint

3j.

The liquid is allowed to evaporate on the skin, and the lotion repeated as often as possible by the patient himself, during the day.

HÆMOPTYSIS.

Prof. Davezac, of Bordeaux, has treated with success of gunshot injury to the brain, supported the views of hemoptysis in two tuberculous patients with sub-

cutaneous injections of serum and gelatine (2 per cent.). In one case he injected into the outside of the thigh five cubic centimetres (one drachm) of the solution, and the hæmoptysis ceased. Double this dose was injected in the second case, with a similar favourable result.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 6th, 1899.

PRINCIPLES OF TREATMENT OF TUBERCULOSIS OF THE BONES AND JOINTS.

In a paper on this subject in the St. Petersburg Med. Wochensch. Dr. Paul Klemm lays down the following as fundamental points of treatment. Diagnosis in the earliest stages of the disease is of the highest importance. The most important primary treatment is absolute rest of the parts in bed and plaster of paris. On retrogression of the symptoms the plaster of paris dressings may be changed for such as allow of walking. Every manual redressment of any abnormal position involves an uncontrollable serious danger as regards the patient. It is contrary to reason to be a partisan of either operative or conservative treatment. This does not depend on the taste of the surgeon, but on the condition of the patient which demands varied therapeutical measures corresponding to the condition of the diseased limb. Injections of iodoform are highly to be commended, if it is possible to bring the remedy into contact with the diseased parts. Tuberculous suppurations require removal of the pus by puncture or incision, with subsequent treatment by iodoform. Operation is justifiable when febrile movements were present or a suppuration, caused by advance of the tuberculous mischief, threatens to weaken the patient. Typical resection, with the exception of that of the hipjoints, is well avoided; arthro and arthrectomy, as well as local extirpation, should be preferred. In principle the formation of firm ankylosis is to be selected in preference to mobility General treatment is an important factor in the manage. ment of tuberculosis. . The highest ideal requirement in the treatment of surgical tuberculosis lies in the foundation of sanatoria standing midway between holiday colonies and hospitals, open the whole year, and devoted exclusively to the treatment of tuberculosis.

REVOLVER INJURY OF BRAIN AND REMOVAL OF MISSILE.

In connection with the report of a successful case in which the site of the bullet was determined by Röntgen illumination, and thereupon removed, Med. Rat. v. Burckhardt, in the Med. Korrosep. Blatt, des Wurtemb. Ærzt. Landesverein, the operator passed on to discuss the subject from a wider point of view. In 1854 Von Bruns published his work on the surgical diseases of the brain and its coverings. He therein shows that the principle of not searching too minutely for the missile in the brain, as had been shown by numerous observation that the retention was not injurious, was wrong. He was able to show that in the supposed recovered cases, after a lapse of time varying from months to years changes took place, in consequence of the pressure of the bullet, that led to the death of the patient. The collection of Bradford and Smith, which embraced the cases of gunshot injury to the brain, supported the views of mortality of 33 per cent.; where it was left in, a mortality of 54 per cent.

V. Bergmann, in his work "Ueber die Einheilung von Pistolenkugeln im Hirn nebst Bermerkungen zur Behandlung von Schusswunder," advocates strongly abstention from interference in recent injuries where the skin opening is small, and this even in times of fever, except in a few cases, as, for instance, where the meningeal artery is injured, or when symptoms are present of irritation in the neighbourhood of the motor region.

V. Burckhardt, on the other hand, in all cases of bullet injury to the brain, except those in which there is no hope of retaining life, lays open the bullet track. If the track extends into the brain he removes the bullet if its situation can be ascertained, and that is facilitated by the Röntgen rays.

He then cleanses the wound with simple sterilised water, and always leaves in a drainage tube. He attributes great importance to leaving in the drain. He only recommends this plan of treatment, however, in times of peace, where every assistance and all necessary appliances are at hand. If these are not procurable he recommends the course of v. Bergmann, simple aseptic dressing. In the field especially this plan is the only proper one.

THE DEGREE OF DOCTOR OF MEDICINE.

The decree of the Prussian Ministry, according to which the degree of doctor can only be granted after the Staat's examen has been passed, the degree itself not being a legal licence, came into force on October 1st. The other German States have now followed the example of Prussia. The different governments are now seeking to establish uniform regulations for the granting of the M.D. degree.

SCHOOL MEDICAL OFFICERS.

This subject is coming again to the front. The urban School Deputation having laid a series of proposals before the magistracy. These are to the effect that a school medical officer shall be appointed to every six schools; that all children shall be examined before admission; that sick children be examined and certificates granted where necessary; that every fortnight the medical officer shall attend at the school, when the teacher can get advice and children be presented for examination. At the request of the master he must visit the school either during or outside the hours of instruction, and he must communicate with him whatever is amiss. Anything observed can only be published with the consent of the School Board. The honorarium proposed is £25 per annum.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 6th, 1899. RENAL COLIC.

AT the Gesellschaft der Aerzte, Schnitzler exhibited a patient, æt. 18, who had suffered on many occasions from excruciating pain in the left flank, in which a distinct swelling could be felt on palpation. During one of these severe attacks he was brought to hospital, after which it was observed that the quantity of urine was much reduced. This reduction culminated in painful anuria, and finally an operation was decided upon.

After the kidney was exposed, the pelvis was found to be distended by a large number of calculi, one of which had entered the ureter, and become firmly impacted. After their removal the wound was packed with gauze, and the patient rapidly recovered.

It may be well to call attention to a physiological phenomenon in this case which should not have occurred if the dicts of physiologists are to be accepted.

The right kidney was, and still is, perfectly healthy; then why should such painful anuria have arisen, when one kidney can be removed altogether without any bad effects? Reflex action is the positive reply, and this must be accepted in the absence of any other obvious cause. In opening the kidney, Schnitzler advises the incision to be made on the convex margin of the organ, where it always heals up quickly, leaving no fistula.

DISPOSITION AND PREDILECTION.

Hofbauer read a paper to the society on the disposition to, and predilection of, disease in the human organism Many diseases acted particularly on individual organs, either chemically or bacterially, and this could be predicted as soon as the nature of the disease was known. Again, other diseases had a predilection to become metastatic, which was not uncommon in the infectious diseases. The fundamental principle of our assumptions is that a weakening change must be induced in the tissue, probably resembling that of a contused wound where no solution of continuity exists, although severe changes are induced.

It follows as a corollary that these changes form a nidus for the microbe to germinate, and so fortify itself for a successful attack on the whole organism. It is not necessary that the vitality of the cell should be reduced as in inflammatory centres; where the vital force is high we have the same disposition to take up the morbid virus. We are, therefore, forced to the conclusion that there are several factors in "disposition and predilection," but the most potent of these is "active hyperæmia."

Nothnagel complained that Hofbauer had not approached this interesting subject with the comprehensive grasp that it deserved. Before proceeding to discuss "disposition," the properties and conditions of protoplasm, its affinity for and antagonism to poisons which are circulating in the blood should be considered.

Professor Neumann said that it was a notorious fact that the tertiary phenomena of syphilis had a "disposition," or preference, to appear on the site of the secondary efflorescence. He had no doubt that the early changes in the tissue and vessels had reduced the resistance of those structures, rendering them liable to the subsequent attack.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

CHOLEDOCHOTOMY.-Mr. BATTLE operated on a female, æt. about 50, who had been under the care of Dr. Sharkey for symptoms of cholecystitis, which had been considered to be due to the presence of a gall-stone. The attack, about two months before the present admission, had been accompanied by pain over the region of the gall-bladder and some fever. This had subsided, and the patient had returned to her work, but had been compelled to seek re-admission to the hospital on account of a return of the pain in the region of the gall-bladder. She

had not had jaundice, nor was she known to have passed any gall-stone. On examination of the abdomen a rounded swelling the size of an egg could be felt in the right linea semilunaris below the head of the umbilicus. This was very hard, and its surface slightly irregular; it was also very tender. Between this, which was evidently in contact with the abdominal wall, and the liver, there was an area of resonance. It was evident that the gall-bladder was distended and inflamed secondarily to a block in the cystic duct, and this was thought to be a gall-stone. At Mr. Sharkey's request Mr. Battle explored the swelling through an incision in the right linea semilunaris. The gall-bladder was found enlarged and its wall much thickened; it was adherent to the omentum and to the hepatic flexure of the colon. An incision of its fundus (after care had been taken to isolate it from the peritoneal cavity by means of sponges and gauze), gave exit to mucus which was bile stained; the wall was about a fourth of an inch thick and rather friable; no stone was present in the gall-bladder itself, but when the finger was passed along the cystic duct a stone could be felt about four inches from the fundus; the apex of the gall-bladder and its continuation into the duct, as well as the duct itself, was markedly tortuous, and the mucous membrane considerably thickened, for this reason no forceps could be made to grasp the stone when passed from within, as the mucous membrane overlapped it so much. It was considered advisable to incise the duct over the stone and remove the calculus through the opening thus made; this necessitated a rearrangement of the gauze and sponge packing, the use of large retractors and the enlargement of the original incision; even then it was difficult for Mr. Wallace (the Resident Assistant Surgeon) to lift the liver and bring the stone in such a position that the duct could be incised over it, and stitches afterwards put in. A stone about the size of the last joint of the little finger was removed and the duct appeared quite free beyond, so that the stitches were inserted after Lembert's method, and the opening closed. It was considered best to suture the fundus of the bladder to the abdominal wall, and this was done in the usual way. There was some difficulty in attaching the gall-bladder as it readily tore when the sutures were tied at all firmly. A drainage tube was put into the gall-bladder and surrounded with gauze packing. The remainder of the abdominal incision was closed with interrupted sutures in three layers. Mr. Battle said that the tumour before examination at the operation felt as if it were full of gall-stones, the hard irregular surface conveying that impression to the touch. The removal of the stone was difficult, he pointed out, owing to its distance from the surface, whilst the swelling of the mucous membrane prevented its removal from within by means of forceps. Although the duct was apparently completely cleared, it was thought better to drain for a time through the fundus rather than close the opening at once, as it was possible that some swelling of the mucous membrane might result from the manipulation of the forceps.

It is satisfactory to state that the patient has continued to make satisfactory progress since the operation.

ROYAL FREE HOSPITAL.

OPERATION FOR THE RADICAL CURE IN WHICH THE HERNIA WAS ASSOCIATED WITH LATENT TUBERCLE OF THE PERITONEUM AND WITH PERITONEAL CYST.—Mr. BATTLE operated on a boy, ten years of age, for a left scrotal

hernia of some months' duration. Three years ago the patient had undergone an operation elsewhere for the radical cure of a hydrocele of the cord, and the scar of the operation was still visible. The hernia was a reducible one. On opening the sac it was found to contain a little fluid and also a large sized peritoneal cyst with flaccid wall. At the lower part of the sac was some cicatricial tissue, near which was situated a large nodule the size of a split pea; numerous other nodules of smaller size were scattered on the peritoneum lining the sac, and could be felt on the parietal layer when the finger was introduced into the peritoneal cavity. The sac was dissected up and removed, the method of Bassini being employed in closing the opening. Mr. Battle remarked that the general condition of the boy had not led one to suspect the possibility of the condition found, neither was there anything in his family history showing a tendency to tubercle, he had always enjoyed good health, and there had been no abdominal symptoms.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 11, 1899.

STATE REGULATION OF MARRIAGE.-I.

Among the dreams of reformers there is one that has probably been often fondly dwelt upon, though few have had the courage to proclaim it. It is the plan of checking the growth of disease and crime by preventing the engendering of offspring by those who are diseased in body or in mind. In the present state of public opinion such a dream is undoubtedly Utopian, yet "the thoughts of man are widened with the process of the suns"; and who knows whether the twentieth century may not see this somewhat misty dream crystallising into a reality? We should, perhaps, have to look to our cousins across the Atlantic for the actual framing of laws directed to this end; for many plans of social reform have taken bodily shape on that go-ahead soil; and if many of them have, like the Salt

Lake City, become dissolved in the overwhelming tide of popular feeling, some of more substantial structure may perhaps abide. Our contemporary, the Journal of the American Medical Association, has three contributions to the subject in one of its December issues. Dr. A. H. Burr writes on "State Regulation of Marriage for the Prevention of Communicable and Hereditary Diseases;" Dr. T. H. McCassy takes for his theme. "How to Limit the Over-production of Defectives and Criminals;" whilst Dr. D. R. Brower offers "Suggestions on the Limitations and Treatment of Juvenile Criminals." All three papers were read in the section on State Medicine at the forty-ninth annual meeting of the American Medical Association; and among them we may count up four main plans for the improvement of the rising generation, as follows:-1. Better training of children; 2. The reform of punishment so as to make it corrective rather than vindictive; 3. Asexualisation; 4. Regulation of marriage by exacting medical certificates from the contracting parties. Of the first two plans it may be said that there is everything in their favour, and nothing against them; and with this we may dismiss them from present consideration. The plan of asexualisation has no doubt arguments to support it; but there is much to be said on the other side. Dr. McCassy himself acknowledges that it is not reliable. "Oriental people, including the Turks," he says "have tried this treatment among the Eastern eunuchs and have no confidence in it as a method of reform The eunuchs were shameless, melancholic, and often suicidal, as well as defective in courage, gentleness, and remorse." Nevertheless, he advocates the practice, which would, he thinks, speedily limit the dissemination of disease, vice, and crime, if applied to defectives and criminals. He would approve of it also as a punishment for rape; and of this it may at least be said that the punishment would fit the crime. But we venture to affirm that apart from all scientific objections, the rock on which any legislation directed to this end would split, is the one of sentiment in the mind of the public; and that it is no more likely to become a legal practice than would be the provision of a lethal chamber for the suppression of idiots. We have, lastly, the State regulation of marriage. Dr. Brower contends that "the marriage licence, in addition to present requirement. should demand evidence that both parties are in good health, that they are not inebriates, not epileptic, not tuberculous, not insane, not criminals, not paupers, and that they have no active venereal disease." Dr. Burr holds same view, believing that "the public good demands that every candidate presenting himself or herself for a licence to marry should be required to file a certificate of health from a legally qualified examining physician, showing freedom from hereditary diseases, like insanity or epilepsy, from all active tuberculous infections, and from communicable venereal diseases." There is so much involved in these two paragraphs that, to facilitate discussion, we must narrow down the subject. The disqualifica.

tions enumerated fall into three distinct categories: 1. Inebriety, paurerism, and criminality; 2. Insanity, epilepsy, and tuberculosis: 3. Gonorrhœa and syphilis in the communicable stages. Further, any legislation would have two objects in view: (a) The safeguarding of the health of the contracting parties: (b) The prevention of the birth of diseased children. Let us look at each of the three categories in this dual aspect. 1. Inebriates. Paupers, and Criminals: As regards the first of the two objects, the safeguarding of the health of the contracting parties. there is no occasion here for legal interference; for in the first place a person's health is not affected. except quite indirectly, by marrying a drunkard, a criminal, or a pauper; and in the second place, any person marrying such an one must do so with a full knowledge of the fact, and can hardly expect to be relieved of the responsibility of his or her folly. As regards the second object, it may be safely asserted that drunkenness, crime, and pauperism depend for their development much more upon early surroundings than upon heredity; indeed, it is doubtful whether the assignment of responsibility for the fostering of criminal tendencies to heredity is not entirely due to the confusion of hereditary influence with the influence of early vicious environment in the parental home. 2. Insanity, Epilepsy, and Tuberculosis: Here also it may be affirmed that a person's health is not affected by marrying an insane, epileptic or tuberculous individual; so the first object does not apply. On the other hand, there is no doubt that the children of the insane and epileptic have as their heritage a tendency to the development of these and other diseases; and for this reason people so afflicted ought not to marry. But this result is hardly to be attained by legislation; it is rather to be hoped for as the outcome of the education of the laity as to the dangers involved. Moreover, Nature provides her own safeguard for the race by ordaining that families with the taint of insanity tend to extinction. Tuberculosis has to be considered rather by itself. In many cases it does not develop till after marriage, and it would be scarcely practicable to prohibit marriage to persons with a tuberculous history. Further, the children of tuberculous parents may be themselves healthy, especially if due attention be paid to their surroundings. The effective working of such a scheme as that recently approved and patronised by the Prince of Wales will probably do more to limit the spread of this national scourge than could be hoped for from a law preventing the marriage of tuberculous persons. We must reserve the consideration of venereal diseases in an acute stage for a future articleas they occupy a very different position to other diseases in regard to marriage eligibility.

UNCHRISTIAN CHARITY.

THE announcement that managers of the Liverpool Ladies' Charity have decided to enlarge; the scope of the rules so as to admit "in exceptional circumstances, after careful investigation," single

women in their first confinement, brings into painful prominence the cruel and uncharitable rigour of the regulations of the majority of these institutions in respect of unmarried women. In some lying-in hospitals they are altogether placed under a ban and even the more liberal only concede accommodation at a first confinement. Under pretence of withholding assistance from the profligate, the Christian ladies and gentlemen who manage these institutions harden their hearts against sinning but unfortunate women in their hour of need, and leave them to the cold charity of the streets or the workhouse. Is this Christian charity? Certainly not such as we understand it. The true basis of Christian charity is to be found in the parable of the adulterous woman, and we would repeat for the benefit of these good persons the invitation extended to those alone who have not sinned. There is no obvious reason why the ethical standard which obtains in most general hospitals should not also obtain in lying-in institutions. We do not refuse admission to the drunken prostitute who has been run over or who has been badly injured in a public-house brawl. We do not turn away the unrepentant burglar who has broken a limb in some nefarious exploit; nor do we decline to diagnose and treat an applicant who is suffering from cerebral tumour as the result of immorality in the forgotten past. Why, then, this rigour against hapless women whose unhappy fate is often but the outcome of demoralising surroundings and the want of moral training? The whole principle is wrong. Medical charities have to do with patients, not persons, and it is not for us to re-enact the Pharisaic policy of walking by on the other side, avoiding all contact with impurity. Let us scrutinise the fear professed lest the assistance of unmarried women during labour should serve to encourage vice. Do these well-meaning ladies and gentlemen imagine that girls deliberately, and with malice aforethought, become pregnant? Do they suppose that these girls in yielding to vicious instincts are influenced one way or the other by their prospects of admission, should occasion arise, into a lying-in hospital? No, if a girl becomes pregnant, her first thought is to rid herself of her burden, even at the price of health and even life itself, and it ought to be our object to stem the rising tide of infanticide by providing an asylum for women who are tempted by so many, and such grave reasons to resort to criminal practices in order to obviate the prospect of having to trespass on the grudging hospitality of the lying-in hospital. The same well-meaning but misguided policy forbids the admission into the wards of our general hospitals of women suffering from primary syphilis, with the result that thousands of women who would gladly avail themselves of an opportunity to place themselves under treatment are thrown back on the streets, there to infect countless thousands of the incontinent who, in their turn, infect many innocent and otherwise respectable persons. This pseudo-morality, which is as unchristian as it is cruel, should be cast aside in favour of a higher and more enlightened conception

of our duties and responsibilities towards the frail and the unfortunate. There can be no better opportunity of obtaining a hold on these women than at such a time. Their spirit is broken by the sufferings incidental to their condition, they realise, perhaps for the first time, that the ways of the transgressor are hard, and the moment is a favourable one for appealing to whatever good remains in their nature. The hospital, indeed, is not the proper place for respectable married women. People should not be encouraged to marry until they are in a position to face this necessary sequel of marriage, and it is a sorry service to them to entice them into engagements which they are not in a position to fulfil. We can understand a maternity charity to providing medical attendance for married women at their homes when circumstances justify this course, though even then the door is opened wide to the most flagrant abuse. The great argument however is, after all, that it is sheer brutality to refuse admission to a woman in labour simply because she is unprovided with her marriage lines or because experience has not imparted to her the virtue of continence. The profligate do not have children, or in but small proportion; it is the silly artless girl whose passions are stronger than her reason, who commits herself, and her fate should appeal to us quite irrespective of her moral status.

Comment le sauriez vous, âme chaste et tranquille A qui la vie est douce et la vertu facile. . . Vous ne comprenez pas, n'ayant jamais eu faim Qu'on renonce à l'honneur pour un morceau de pain.

SCHOLASTIC HYGIENE.

ONE of the most noteworthy discoveries of late years in connection with the spread of disease was the recognition of the influence of schools in the propagation of certain infectious diseases. Even now. authorities are not unanimously agreed as to the influence of school aggregation in the dissemination of diphtheria in spite of the most conclusive statistics and of the fact that common sense would lead one to expect that every social circumstance which brings children into more or less intimate contact must needs favour the inter-communication of all diseases, including diphtheria, that are susceptible of this method of transmission. The law compels parents to expose their offspring to the risks inseparable from school life under existing conditions, with the result that a very large proportion of the money spent in isolating cases of infectious disease when discovered is wasted for the simple reason that very mild cases escape recognition, and therefore notification, though fully capable of infecting their immediate surround-The habits of very young children and the promiscuous use of lavatory and other appliances and utensils offer every facility for the propagation of disease, and as we can hardly hope to eradicate these habits some other means must be found to lessen the risks entailed by these huge aggregations of highly inflammable material. First of all, it is important that the

teachers should be instructed in the principles of hygiene, so that they may be enabled to take an intelligent interest in the application of the principles to school life. The subject ought to be made a compulsory one, or, failing this, special inducements should be offered to them to acquire a knowledge thereof by providing courses of lecturers by competent men, and by making efficiency in this subject a passport to advancement. A practical knowledge of this subject is conceivably more important in the teacher at an elementary school than the possession of an university degree, seeing that the one is of immediate practical importance, while the other, at any rate for primary schools, is not. We have already mentioned that the control at present exercised over the spread of the disease among the young is largely inoperative because of the fact that the disease may escape recognition for a time or, if mild, even altogether, leaving the sufferers free to spread disease far and wide without let or hindrance. The only effectual way of obtaining information respecting this class of cases is the systematic examination of scholars by a medical officer appointed for that purpose. There is the less reason for delaying this measure seeing that in other respects medical inspection of the scholars is eminently desirable, notably in regard to defects of the eyesight and other special senses, as well as in regard to physical and mental shortcomings of a nature to call for special appliances and care. This obligation is beginning to be dimly recognised, but we are not yet, apparently, within measurable distance of the school medical officer becoming an established institution. The question of expense is unworthy of serious attention, first, because, as education is compulsory, it is the duty of the State to eliminate all avoidable risks, and, secondly, because prevention is always cheaper and more satisfactory than cure: Among the minor but nevertheless important precautions the use of slates, slate pencils, and sponges ought to be forbidden. Slates have long been incriminated as possibly fertile sources of contazion, in fact, as generally used, they are often plate cultures of pathogenic microbes. Lead pencils and pens should take their place, and each scholar should be taught jealously to keep his writing utensils for his personal use, the loan or transference thereof being strictly forbidden. All school property belonging to a scholar known to be suffering from an infectious disease left in a school should be forthwith destroyed or disinfected, and all books regularly taken home by pupils should be covered in brown paper, such covering to be renewed at stated intervals. Lastly, the school premises should be so constructed as to be readily and thoroughly pleaned and the process of cleansing, at frequent and stated intervals, be effectually supervised by a responsible person. It is only by attention to such details as these that we can hope to stem the tide of disease and to reduce the mortality from this source. We cannot possibly remain with folded arms in presence of these unquestionable risks. Medical control is indispensable if we are to eliminate foci of infection and to graduate the measure of instruction to the intellec-

tual calibre of each pupil. There are signs of the evolution of a healthy public opinion on these points, and in time no doubt sufficient pressure will be brought to bear to compel the attention which the subject requires and deserves.

Aotes on Current Topics.

The Royal Army Medical Corps.

In a letter signed "Pirwane," addressed to the Daily Graphic, the writer calls attention to certain facts that should be borne in mind by the fathers of young doctors aspiring to a military career. recent warrant, although, perhaps, doing all that was necessary and desirable in the matter of corps and rank did not deal with anything else. It did not remove any of the anomalies referred to in the letter quoted. The chief among these are the financial lossincurred by junior officers of the R.A.M.C. serving in India, the withholding of travelling allowance from officers in India, nothwithstanding the frequent moves to which the junior officers in particular are subjected, the withholding of horse allowance from officers under field rank in India, where the climate and extent of ground to be covered render a horse an absolute necessity for the proper performance of the duties, and the refusal to grant a charge allowance toofficers in charge of station and section hospitals in cantonments, and of section field hospitals on active service. These are obviously unjust, and might easily berectified. It might be thought that the mere pointing out of these defects to the Government would ensure their removal. We know of the case of a medical officer who contracted fever owing to hisendeavouring to perform his sanitary duties in cantonments on foot. Had he waited till the cool (?) of the evening to make his inspections he could not possibly have got through with his work. Oneprinciple in the Army is the more responsibility the more pay. Yet medical officers (R.A.M.C.) in charge of large station hospitals, or section hospitals, or section field hospitals, receive no extra remuneration; regimental officers on detached command, or performing duties of quartermaster, paymaster, &c., draw extra pay. Indian medical officers detached in charge of sections of native field hospitals, under identically the same circumstances as British field. hospitals, receive extra pay. Why, then, not officers of the R.A.M.C.? It is sincerely to be hoped that these matters will be properly adjusted so that the cadre of officers of the R.A.M.C may be filled without unnecessary delay.

The Life Risks of Soldiers.

An interesting paper is communicated to the December number of the United Service Magazine by Captain Triggs, the purpose of which is to show that the rates charged by insurance companies on the lives of military officers is excessive. The author points out that, whereas the mortality of officers on foreign service is 15 per 1,000 annually, that of such officers on home duty is only 5 per 1,000. Thus the

mean of the greatest and least risks is only 10 per 1,000, which is admittedly not greater than that of the best lives, on an average, at home. Nevertheless he complains that the insurance companies, while they impose heavy risks upon officers going abroad, make no abatement for them when at home, although, in consequence of the physical examination to which they have been subjected before admission to the Service, and in consequence of the very favourable conditions of their lives when at peace and at home, they may be regarded as very choice lives for the insurer. As to the risks of officers in actual war service, he points out that chances of death vary enormously, having been in the South African war of 1879, 64 per 1,000, and in the Egyptian campaign of 1885, only 1 per 1,000. Captain Triggs also dwells upon the fact that, of late years, the risks of transport and of foreign service has been greatly reduced, the carriage of troops being now almost as rapid, certain, and salubrious as that of passengers by the best liners, and the sanitary arrangements both at sea and in station being infinitely safer for the soldier than they ever were previously. The exceptional risk of a general war might readily be covered by an additional rate, for the time, of 5 per cent.

A New Midwives' Bill.

Some more tinkering has been attempted in the direction of legislation for midwives. A new Bill has been drafted by the so-called Midwives' Bill Committee. In orief, the Bill provides that henceforth no woman shall call herself, or habitually practice for gain, as a midwife unless she has obtained a licence; and that in order to be licensed, she must inter alia produce evidence either (1) of having undergone a proper training and subsequent examination, or (2) of having (at the time of the passing of the Bill) been in bona-fide practice as a midwife. The Bill does not render it illegal for any person to assist a lying-in woman in an emergency. A central midwives' board is constituted under the Bill, the chief duties of which will be (1) to organise examinations of a uniform standard; (2) to regulate, supervise, and restrict within due limits the practice of midwives; and (3) to investigate charges of malpraxis, negligence, or ignorance against midwives. Furthermore midwives under the Bill are licensed, and not registered; also the habitual practice of midwifery for gain, by women not licensed, is declared to be illegal; lastly, the area within which a midwife may practice is, in order to facilitate supervision, limited to that of the local supervising authority from whom she has obtained a certificate authorising her to practice. We note also that the Bill is not intended to apply to Scotland or Ireland, and that nothing in it applies to legally qualified medical practitioners. Inasmuch as the Bill has been drafted in accordance with the recommendations of the General Medical Council, there is likely to be less opposition to it on the part of the profession than has been the case on former occasions. There is some difference between a "Licensed" midwife and a "Registered" one, at all events in name, and this, such as it is, may dispose of the fear that the proposed new legislation will have the effect of introducing an inferior order of medical practitioners which has always been the primary objection to previous attempts of the kind. We have not space to publish the Bill in extenso; but those of our readers who are interested in the subject may obtain a copy of it by applying to Messrs. Howell and Co., 87 Malden Road, Kentish Town, enclosing two penny stamps.

The Abuse of Friendly Societies in Australasia.

THE Intercolonial Medical Conference, summoned to consider the relations between the medical profession and the friendly societies, met in Melbourne in November last, and several important resolutions were discussed and adopted. It will be remembered that, as a preliminary step to holding the congress, a schedule of questions was issued to all the practitioners in the colonies bearing upon the points at issue, and replies were invited thereto. Question No. 9 inquired for information respecting well-to-do patients who belonged to the friendly societies, and the evi. dence forthcoming upon this subject was remarkable. A few examples are here appended: "A leading banker, with £5,000 per annum"; "A retired publican, worth £20,000"; "a hotel-keeper, worth £5,000 (he paid a Melbourne consulant 50 guineas for one visit," "a solicitor, worth £1,600 per annum, who is also a large property owner." "A gentleman with probably the largest produce business in Victoria, ex-Mayor, splendid mansion in suburbs, pays me 14s. 6d. per annum." "I have attended as a lodge patient a man worth £70,000." According to the societies' rules, all the members are attended for an inclusive sum of 3d. per week; that is to say all the rich patients above mentioned had for this sum a medical man at their beck and call throughout the year. The Intercolonial Medical Journal of Australasia, in discussing these facts in the November issue, asserts that the abuses of the friendly society system are of such a pronounced nature that it is a matter of astonishment that the practitioners concerned should have submitted to them for so long.

A Case of Poisoning by Hyssop.

An inquest held last week at Birmingham on a woman who had died after taking an infusion of hyssop, and the case is of interest inasmuch as no previous case of death from this cause has, as far as we are aware, been recorded in this country. It seems that the deceased had taken hyssop during labour on a previous occasion on the advice contained in an old medical work in her possession. She was expecting to be confined again on the 31st ult., and sent for a penny packet of hyssop, of which she drank an infusion. Serious symptoms soon followed, and Dr Leech was sent for, but was unable to avert the fatal result. The chemist who sold the drug stated that the packet contained fifteen doses. Dr. Leech described the symptoms from which the woman was

suffering when he was called to her. The lips were blue, the complexion dusky, and the hands were swollen. Labour was in progress, and the child was still-born. He had been unable to find any record of a similar occurrence in English literature, but he mentioned that in a French medical work which he had consulted he found an account of three deaths from taking hyssop (hyssopus officinale, N. O. labiatæ), adding that a series of experiments on dogs showed that a much smaller dose than that taken by the deceased proved fatal to these animals. The dose actually taken in this instance was about 160 grains, including a large proportion of the flowers. A verdict of death from misadventure was returned.

The Fever Scare at Nice.

Our correspondent in the Riviera, alluding to the rumours that typhoid is unusually prevalent this year in that part of France, throws discredit upon their authenticity, and relates an anecdote which may or may not afford an explanation of their currency. Such information as we have been enabled to obtain from private sources lends colour to the view that these rumours are the outcome of the mischievous tendency which afflicts so many people to write about things of which they know little On the other hand, the French or nothing. have largely themselves to thank if such tactics prove successful in deterring travellers from visiting their sunny south. Reading between the lines, the denials of the authorities amount to this: "There is no typhoid fever, and if there were, we should say the same thing." It is, indeed, the fatal policy of persistently disguising matters of this sort until further secrecy is impossible that has shaken public confidence in duly authorised reassuring statements. In England, thanks to our system of notification, such tactics are impracticable, and the authorities of European health resorts in favour with English and American travellers will do well to inaugurate a system which will enable them to authenticate their statements by statistics which shall command confidence.

Consumptives as Hotel Visitors.

THE Bournemouth Guardian is naturally not a little agitated and distressed by a letter signed "Bournemouth," recently published in a London newspaper. The writer stated that a man in the last stages of consumption left his hotel, and that "within an hour from his leaving the room it was re-let, this time to a young lady." It is not clear that the incident thus narrated happened in Bournemouth, although the local editor evidently regards the matter in that light. Behind it all, however, lies the bare skeleton of a grisly tragedy that is being enacted every day of our lives, not only in the hotels of Great Britain, but throughout the civilized world. From the very nature of things a certain percentage of the travelling public must always, consciously or unconsciously, be affected with communicable diseases. To the credit of hotel management generally, it may be believed that the systematic order and cleanliness

which stamps the latterday regime reduces to a minimum the risk of these undesirable infectious legacies from visitor to visitor. Fortunately, although phthisis is due to a specific bacillus, its ordinary routes of infection are such that it is not likely to be communicated in a bedroom that has been thoroughly cleaned and provided with clean bedding. At the same time it would be advisable, wherever possible, to disinfect the room and its contents. To put the matter plainly, an hotel patient is not likely to spit about his bedroom, and it is in the sputa that the chief danger lies. The public require education upon these points, for there can be no doubt that many worthy persons sin in ignorance, and have not the least idea they may hand on their terrible malady to others. We trust the day may not be far distant when every self-respecting sufferer from pulmonary consumption will carry a small spit-flask charged with some antiseptic to disinfect the sputa.

The Plague at Madagascar.

THE plague continues to rage at Madagascar, but fortunately it does not show any tendency to spread far from the regions where it first made its appear. ance. Since the beginning of November, at which date the epidemic broke out, there have been in all 204 cases, with 132 deaths. This number is made up of 23 creoles, 69 natives, 39 Asiatics, and 2 Europeans. A sanitary cordon is rigorously applied around Tamatava, and the great Government works are at a standstill. The capital has been placed under medical control, and drastic sanitary measures are strictly enforced.

Poor-law Barbarity.

Bumbledom, although happily more or less scotched, is, nevertheless, far from dead. The guiding principle that has prevailed under the régime of Sir Hugh Owen has been to make administration a harsh and repulsive, iron-bound system, with a view apparently, of frightening persons out of becoming or of remaining paupers. An excellent illustration of this position is afforded by the Marylebone Board of Guardians, who, in return for a night's lodging demand from a "casual" the breaking of ten hundredweight of stones or the grinding of ten pecks of corn. To perform that tas's means nine hours hard and continuous work. How an ill-fed man is to make that effort without sooner or later wrecking his constitution is a problem that does not appear to have entered into the consideration of the Marylebone Board. For a well-fed and strong man to set about such a labour would be unwise, and a thousand times more so for the tramp who is usually physically unfit for any sustained laborious work. There can be little doubt that many forms of aneurysm and other kinds of circulatory diseases, to say nothing of varying organic mischief, might be set up by the imposition of arduous manual work upon the waifs and strays of the casual ward. We say nothing about the iniquity of making a profit out of this pathetic class of human wreckage, for that is the effect of demanding a day's labour in return for

accommodation worth no more than a few pence. When shall we have a Local Government Board that will fix and control such matters as diet, exercise, and labour upon some scientifically ascertained medical data?

Adulterated Milk.

Or all the mean and persistent frauds perpetrated upon the community there is none more cruel and deserving of condign punishment than the adulteration of food. To add to the irony of the thing, the offence can be readily detected, and all the legal machinery for successful prosecution is at hand. Therefore, it is, above all things, preventible; yet, like infectious diseases, it is not prevented. Take the case of milk, the adulteration of which is, beyond a doubt, carried on to an enormous extent throughout the kingdom, largely at the expense of the poor. This fraudulent practice is the source of profits that would make the mouth of an average Jew water, so that it is not surprising that certain milk-vendors are ready to encounter the odium and loss of repeated fines. At the Thames Police Court, last week, an old offender in that direction was fined £6, but we venture to suggest that the penalties inflicted should be rapidly cumulative in severity up to a certain point, when they should invariably be replaced by a long term of imprisonment. The present apathy of vestries has much to do with the prevalence of milk frauds. It is to be hoped that the new spirit of the Local Government will tackle this subject of adulteration firmly, and begin by overhauling the Somerset House analyst's department.

Corporal Punishment of Lunatic Patients.

THE Hoxton House Lunatic Asylum has recently come in for an unpleasant share of public attention in connection with a police-court case. A female attendant at that institution was charged with assaulting two of the patients, and it was proved that she whipped both of them in a bathroom with a cane, one on the body, the other on the hands. She did not report the circumstance to anyone The magistrate in authority at the Asylum. remarked that no doubt the patients were exceedingly troublesome, but, as they did not know what they were doing, it was all the more imperative that they should have the kindest treatment. He allowed the defendant the full benefit of the Act by imposing the lowest penalty-namely, 40s. in each case. One would hardly imagine that nowadays such a barbarity as the whipping of lunatics could have existed outside the pages of a novel. What would the late Charles Reade have said of this Hoxton lunatic attendant with her harridan temper?

Medical Fees at Inquests.

In a letter addressed to the Western Morning News, Mr. Waterfield, practising at Stonehouse, calls attention to an anomaly in the payment of fees to medical witnesses at inquests, of which we must confess we were previously ignorant. Having been called upon to give evidence on two occasions - the inquest having

been adjourned—he naturally expected to receive two fees, but, to his surprise, he was informed that however many attendances a medical witness may put in, he can only claim one fee. This decision is rendered the more absurd by the fact that the jury receive double sets of fees, but on the matter being referred to the County Council, the coroner's decision was confirmed. Mr. Waterfield suggests that in future the only course will be for medical witnesses to refuse to give evidence on the second occasion before being paid their second fee, but in view of the powers possessed by the coroner to compel witnesses to answer questions, we doubt if this method would prove successful. The matter is one which should be taken up by some organised body of medical men with the view, first of all, of testing the legality of the decision, and if this be established to obtain an amendment of the law the injustice whereof is obvious.

A Worm-Infected Gaol.

Some interesting and curious facts have just been published by Captain Fearnside, I.M.S., regarding the cause of a high mortality rate in one of the prisons in India, that at Cananore, with which he was connected. Before Dr. Fearnside took charge the death rate among the inmates from intestinal disorders had been very high for many years; in 1893, for example, the mortality was as much as 47 per 1,000 from this cause alone. However, while making a post-mortem examination upon a prisoner in 1894, who haldied of diarrhoea, he found a mass of 37 round worms at the ileo-cocal valve. Acting upon this hint he afterwards resorted freely to the use of santonin, as the result of which the cases of diarrhoa. enteritis, and dysentery at once underwent a considerable reduction. As showing the remarkable prevalence of the parasite in the gaol, he states that in 1896, 255 prisoners passed between them the huge number of 2,703 worms, an average of ten each. This plague of worms does not so far appear to have been amenable to preventive measures.

When Chloroform is to be Preferred.

DR. MIRON I. MARSH, in discussing the conditions in which chloroform is to be preferred as an anæsthetic insists on the following:-In organic diseases of the nervous system and in atheroma occurring in persons of advanced years. In chronic or acute inflammatory affections of the respiratory tract, such as severe bronchitis, asthma, emphysema, or advanced tuberculosis. Also in protracted operations about the nose, mouth, or pharynx, which necessitate the nose and mouth being uncovered. In operations performed with artificial light (other than the electric incandescent), unless the source of illumination is at a sufficient distance. Even with chloroform, however, it is undesirable to operate in the vicinity of gas lights on account of the irritating vapour to which its decomposition gives rise. The same reason applies when the galvanic cautery is to be used in the neighbourhood of air passages. Chloroform is preferable to ether in all cases of renal disease, whether acute or chronic, in chronic alcoholism, and

in both infancy and old age. It is much better than ether during labour, and in puerperal eclampsia when an immediate effect is required.

Changes in the Blood after Removal of the Thyroid.

EVERY detail-chemical, physiological, and pathological-bearing on the effects of removal of the thyroid gland is of interest in view of the importance which this gland has of late assumed in physiology and therapeutics. Dr. A. G. Levy has recently published the results of a series of observations made by him on the changes induced in the blood of dogs by removal of this organ. It is generally recognised that the numerous and diverse phenomena following removal of the thyroid are caused primarily by a pathological condition of the blood. This pathological condition consists in the absence from the blood of a thyroid secretion which is necessary either to the normal metabolism of the tissues or for the purpose of neutralising some poisonous product or products of metabolism. The most salient feature of his results is their inconstancy, and this indeed applies to all the phenomena following thyroidectomy. It is striking how one symptom often predominates over others, sometimes even to the exclusion of the others. A diminution either in hæmoglobin or red corpuscles, or in both, is a usual but not invariable result, but there does not appear to be any direct relationship between the intensity of the ansemia thus induced and the severity of the symptoms in general. The proportion of white corpuscles undergoes manifest increase almost from the first, and the specific gravity of the blood always falls after thyroidectomy, as might be inferred from the existence of anæmia. The percentage of fibrin in the blood of a thyroidectomised animal is invariably found to be increased, sometimes to a considerable extent. With regard to the solid constituents of the blood there appears to be a varying loss of certain non-proteid substances and a varying gain in others. for throughout the proportion of loss of proteids to that of solids is inconstant. It follows that an exact determination of the conditions which tend to produce in some dogs a partial immunity from the evil effects of thyroidectomy is still to be effected, but it may be assumed that irregularities in the quantitative changes in the blood of different animals after thyroidectomy are analogous to the variation in the general symptoms which result therefrom.

The Unqualified Dispenser.

A woman died at Stockport last week from the effects of an overdose of morphia contained in medicine. The medical man in attendance states that his dispenser made a mistake in making up his prescription, he having put in fifty grains of morphine instead of one and a half. We should infer from this that the dispenser must have been totally ignorant of the lethal properties of large doses of the drug or he would not have committed such a fatal blunder. It is a fact that few, if any, of the dispensers employed by medical men have had any training to fit them

for the duties and responsibilities they undertake, but as medical men technically do not "sell" their medicines, unless they happen to keep an open surgery, the Pharmacy Act does not apply to their establishments.

Fleas as Plague Carriers.

JUST as the common fly and the mosquito have been accused as being disease carriers, so a similar role is now being attributed to the ubiquitous flea. The particular disease for the dissemination of which the flea is being made responsible is the plague in India. The insect it is stated, absorbs the bacillus. and then takes the first opportunity, in the ordinary course of business, of discharging the micro-organism into the blood of a human being. Researches upon this subject have been undertaken by M. Simond. and the results published in the Annals of the Pasteur Institute. Whether the latter be accepted as trustworthy or not, the suggestion is nevertheless one which is worthy of full inquiry by independent M. Simond claims to have determined by his investigations that the plague is only with extreme difficulty propagated by infection through the digestive tract, and that it is very exceptional for the disease to be disseminated by contact with cutaneous wounds or through infection of the mucous membrane of the lungs. Hence it would seem that by the method of exclusion, the author has been led to attribute the dissemination of the disease to the pulex irritans.

Pulmonary Asymmetry.

AT an inquest held on Wednesday last at Bermondsey on the body of a man who had succumbed to the rupture of an aneurism, Dr. Mulqueen, who made the post-mortem examination, stated that the deceased had only one lung, the deficiency being evidently congenital. This one lung seems to have answered the purpose however, for the deceased was 42 years of age, and had never complained of any respiratory trouble. It is to be hoped that this apparently unique abnormality will receive the attention which it merits by reason of its scientific interest.

What is the Lunacy Law?

THE conclusion of the case at Kingston-on-Thames, when a medical man was indicted for having received a lunatic in an unlicensed house, comes as a surprise. An eminent lunacy expert came forward and stated that the action of the accused met with his sanction, and further admitted that he had started a subscription fund in a medical journal to defend the present This appears to amount to an open defiance of the law, which is based on a sufficiently clear and sound principle, namely, to prevent possible fraud and infringement of personal liberty in unlicensed houses. We confess it seems to us a mystery how any man of standing in the medical profession could come forward and practically impeach that administrative position and advise illegal opposition to the Lunacy Acts. Perhaps there may be some explanatory circumstances, legal or otherwise, with which we are not acquainted. Any way, the counsel for the prosecution stated that his sole object was to ensure respect for the provisions of the Lunacy Act. That being so, an appeal may be confidently expected from the acquittal returned by the jury in this case at the Surrey Quarter Sessions.

The Ninth International Congress of Ophthalmology.

The Ninth International Congress of Ophthalmology will take place in Utrecht on August 14th,
and four following days. The work of the session
will be divided into three sections: (1) anatomy,
patholo.ical anatomy, and bacteriology; (2) optics
and physiology; (3) clinical methods and operations.
The committee of organisation of the Congress are
as follows:—President, Dr. Argyll Robertson, of
Edinburgh; Secretary-General, Mr. George A. Berry,
of Edinburgh; and Professor M. E. Mulder, Professor M. Straub, Professor W. Koster, Professor H.
Snellen. The official languages will be English,
French, and German.

Court Appointments.

THE Queen has appointed Sir Richard Douglas Powell, Bart., M.D.. F.R.C.P. to be one of her Majesty's Physicians in Ordinary, in succession to the late Sir William Jenner. Dr. James E. Pollock, and Dr. Thomas Barlow, Physician to the Household, have been nominated Physicians Extraordinary to her Majesty.

"In arduis fidelis" is to be the new motto of the Royal Army Medical Corps. The old familiar emblem of the serpent and rod, representing the art and practice of medicine, is to be discarded, and replaced by the serpent alone as the future badge of the newly-created corps. This latter, with the motto already given, is to be entwined in a laurel wreath surmounted by the Royal crown.

LORD LISTER, P.R.S., has been awarded the Harben gold medal for 1899, of the Royal Institute of Public Health, in recognition of his eminent services to preventive medicine.

DR. JOHN B. HAMILTON, of Chicago, editor of the Journal of the American Medical Association, died on Christmas Eve last. He was 51 years of age, and at the time of his death was Prefessor of Surgery in the Rush Medical College, Chicago. The cause of death was some acute abdominal disorder, for which an operation was performed.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE INEBRIATE'S ACT, 1898.—This important statute came into operation on January 1st, 1899. Meantime a committee, to frame regulations for the proposed Inebriate Reformatories in Scotland, and generally to advise the Secretary for Scotland as to the methods of working the Act, is sitting. At first there was no medical man on that committee. The Royal Colleges of Physicians and Surgeons of Edinburgh and the Glasgow Faculty of Physicians and Surgeons pointed out this

omission to his Lordship, who at once requested the presidents of those Corporations to name a medical man who "would command the confidence of the profession." They nominated Dr. Clouston, who accordingly has been added to the committe.

GLASGOW ROYAL INFIRMARY. -- Lately this institution has with its sister institutions come in for very large sums for extension, the last donation being for £1,000 from Mrs. John Elder, who by her munificent gifts has already placed Queen Margaret College on a firm foundation, and succeeded in raising sufficient funds in addition to establish the anatomical and other practical departments of the College. The other large sums left to the Infirmary were bequests from deceased friends to the institution. Besides these, which have been re-ceived as bequests and donations, the public have liberally subscribed, the latter may, however, be considered as for current expenses, in other words, what the directors name ordinary expenses, and may be used up in defraying the extravagance in which the institution is carried on, and no doubt at the next annual meeting the report will as usual show a deficiency both in the ordinary and also in the extraordinary accounts. Year after year these expenses increase. How is it? Is it because the present class of nurses is of a higher standard? The patients' ailments greater and more serious and severe than formerly? or that the "bacilli," the "bacteria," and the endless variety of "vibriones," "micrococci," et hoc genus are more expensive to kill and destroy them than formerly? Microbes get the blame for a great many things done nowadays, although the invisible atoms may be innocent. In these remarks we may be stirring up a hornet's nest, but this may be remedied by the simple process of crushing the said hornets. We have no wish to lessen the good that the Royal or any of the infirmaries are doing or may do, but it may be stated as a fact that patients have left the infirmary simply because after going they not only obtain insufficient aliment but are passed over from day to day with-out treatment. The matter and reason that such obtains should be well looked into, but we fear will never take place as there is such an exclusive tenure of office of all the officials.

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last (January 9th) was devoted to a paper by Sir William Broadbent, on "The Conduct of the Heart in the Face of Difficulties." He pointed out that a very large proportion of the cases of functional disturbance of the heart's action were due to interference from without, as from a distended stomach and the like. More serious was the condition engendered by peripheral obstacles as when there was high arterial tension. He insisted on the extreme susceptibility of the heart to changes affecting the nervous system, and said it behoved them in each case to distinguish which of the two factors, nervous and gastric, predominated, the better to direct treatment. He laid down the cardinal principle in the treatment of cardiac affections, whether functional or organic, that much more relief could usually be afforded by devising means of reducing the stress or eliminating obstacles than by directly stimulating the heart to overcome them. He empl:asised the value of venesection in the treatment of heart affections associated with heightening of blood pressure in the veins and right heart, especially if followed up by a calomel purge.

Dr. Sansom insisted on the importance of the nervous factor in disturbance of cardiac function, and pointed out that the condition of the heart muscle was less important than was usually held. He alluded to the ill-effects of administering digitalis when the heart was under stress and concurred in the view that the great thing was to relieve rather than overcome that stress.

Dr. T. WILLIAMS related cases to show the influence of a dilated stomach on the cardiac function, and Dr. MORRISON pointed out that the three factors in producing cardiac disturbance were the muscle, the nervous system and the blood, any one of which might predominate in a given case.

Dr. Symes Thompson pointed out the grave significance

of irregularity of the Leart's action, though the patient's feelings in this respect were no guide to the severity of

Dr. MACGUIRE discussed the assistance of the heart's action afforded by the negative pressure developed on inspiration and explained the existence of the exaggerated short breathedness in emphysematous persons by the reduction of this negative pressure. He also explained the production of the pulsus parodoxus in the same way, as the effect of this negative pressure on a weakened ventricle.

Dr. Calvert mentioned that senega, which was usually described as a stimulating expectorant, and was given in cases of chronic bronchitis, was contra-indicated in the presence of cardiac complications by reason of its depressing action on the organ.

Dr. Robert Jones asked what was the relationship between the heart and the action of certain toxins, particularly the toxins of fatigue.

Sir WILLIAM BROADBENT then replied.

Correspondence

We do not hold ourselves responsible for the opinions of our

THE MARRIAGE OF OVARIOTOMISED PATIENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIE,—There is a strange omission in the line of argument you adopt in your leader on this subject, one of much importance, and for its illustration we may take the least complicated illustration at hand, a case of rapidly growing double cystoma; such as cystic disease of both ovaries, or of soft cedematous myoma in a young woman. Of such I have a large collection of stories I could tell you if space permitted, which I think would prove that your view is wrong alike in the eyes of the church, the law, and of mankind.

The argument used by the United States Court is perfectly sound, and the position in which a woman is placed by senile atrophy is perfectly analogous. I have already, and in your own columns, narrated one instance in such full detail that I regret to say the case was identified by some persons interested, and I had a mild reproof for the fulness with which the case was given. It was a case where I convinced a prince of the Church that he was wrong in prohibiting the marriage of a young lady from whom the appendages had been removed, when he himself had performed the marriage ceremony when the bride had long since passed child-bearing. So much for the Church, and by Church I, of course, mean that of Rome, the only church which has ever discussed and drawn up decisions on such questions.

I have a large number of stories I could tell you of the chivalry of men, many of the stories being extremely pathetic in detail, who not only married the women to whom they were engaged after it was explained to them that surgery had removed the last surviving hope of maternity, but of many who have had to be consulted as to the performance of such an operation, and who have willingly consented to a measure of necessity for the benefit of the women they loved, for the saving of their lives. I never knew one of those men break his

troth. So much for the opinion of men.

As for the law, the principle of the law on the matter in question is clear as day in England. If the husband could claim a reduction of the marriage, it could only be when fraud was perpetrated upon him deliberately, when he could prove that knowing that some operation had been performed on his intended wife he asked if both ovaries had been removed, he was informed that only one had been, or that nothing had been done to interfere with her chances of becoming a mother. But even here the difficulty would arise in the question. Would the disease for which the operation was performed have already induced sterility! and we should have to answer, certainly, in the two cases I have taken as illustrations, and in certainly ninety-five per cent. of the cases in which removal of the

appendages should be performed. Because, if this were not considered and this is the serious omission you make. we should have to decide that the cure of disease should result in divorce, whilst the disease itself would not.

One in six of all adult women in England who marry prove to be sterile. A very large mass of these cases derive their sterility from agreet of growth of the uterus—infantile uterus. They do not know of any reason why they should not marry, and they marry and lead sterile lives. They are anxious to become mothers, and they wander from one obstetric physician to another, till some one divides the cervix and puts in a stem pessary, after which the case takes a surgical aspect, becomes one of double pyosalpinx, and the appendages are removed. These cases have come to me in hundreds. I operated on one yesterday, and I have seen two fresh ones this morning. The original disease or deformity caused the sterility, and should be as much a reason for annulling a marriage as the stem pessary, which made the sterility perfectly certain or the subsequent and necessary removal of the deformed and diseased organs. So with cystic ovaries. I have known them in existence long before marriage, and marriage take place while they were in a quiescent condition. Subsequent growth rapidly involved double ovariotomy and confirmed the already existent sterilisation. But what a preposterous proposal it would appear to any Court of Law, to the merest tyro of a lawyer, to suggest that the remedy should justify a divorce decree, whilst the disease should not. The fact of the matter is that it is persistently ignored that the diseases for which ovaries and tubes are removed have already destroyed all chances of maternity, and that the surgical inter-ference only confirms what the disease has already established.

To rule our divorce law in any other direction than that I have indicated would be to go back to the old law of the Jew, in which sterility was ample justification for putting away one wife and taking a few more. Whether this would prove a happy reversion I do not know, but it is a step our law-makers are not at all likely to take.

I am. Sir. yours truly. LAWSON TAIT.

195, Newhall Street, Birmingham.

HÆMORRHAGE IN INTERNAL URETHROTOMY. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I regret that through pressure of work I was unable to reply in last week's MEDICAL PRESS AND. CIRCULAR to the letter of Mr. Myles published in the issue of December 24th on the above subject.

In calling attention to the danger of hæmorrhage after internal urethrotomy Mr. Myles was, I consider, perfectly justified; and I am entirely in accord with him in thinking that in the surgical text books and monographs on the subject of stricture of the urethra sufficient attention is not directed to this danger, or the means by which that it may be successfully combated. It was for this reason that, in my criticism of his original paper, I gave in the Journal of December 21st full details of a case of alarmhæmorrhage that had occurred in my own practice after performing this operation, and of the means that I had found effectual in controlling it.

But my criticisms were entirely directed against his uncompromising condemnation of internal urethrotomy; his views as to the pathology of stricture, what happens when this operation is performed, and the object with which it is undertaken. These criticisms remain unaffected, and are in no way altered by Mr. Myles's explanations, or by his erroneous imagination of my having limited my remarks to stricture in the anterior urethra.

I did not consider it necessary to explain that my criticisms had reference to stricture of the deep urethra, because (1) my remarks were applicable to stricture in any part of the canal; and (2) Mr. Myles specificially limited his observations to stricture in the deep urethra, and it was, of course, to these observations that my criticisms were directed, otherwise they would be meaning-

Mr Myles comes to the conclusion that my remark

had reference only to stricture of the anterior urethera because I use only Teevan's or Civiale's urethrotemer, as a rule; and he then goes on to state:—"I maintain that a stricture of the deep urethra cannot be divided by a Civiale's Instrument or any of its modifications, or by Teevan's urethrotome." Well, I must confess my utter astonishment that a surgeon of Mr. Myles's position and standing should maintain anything so erroneous. Both of these instruments were introduced for, and are capable of, cutting strictures in any part of the canal. Surely Mr. Myles cannot imagine that when, in my paper published in the issue of this journal of December 21st. I referred to 87 internal urethrotomies that I had performed in the previous two and a half years by Civiale's and Teevan's instruments, these were for stricture of the anterior urethra only, and that I am in the habit of dealing with such cases to the exclusion of strictures of the deep urethra.

That both these instruments are capable of dividing strictures in any part of the ureth al canal is witnessed by hundreds of visitors to the operation theatre of St. Peter's Hospital annually, and if Mr. Myles, at his next visit to London, will do me the honour of being present at some of my operations in hospital or private practice, I shall be happy to demonstrate to him the capabilities of these instruments in this direction.

in this direction.

I am, Sir, yours truly,
P. J. FREYER. 46, Harley Street, London, W., January 7th 1899.

"CIDER AND MICROBES." ...

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIE,-Should the statement of the French agricultural chemist, quoted in your journal of the 28th ult, that cider is germicidal prove to be correct, it will explain the freedom from cholera and choleraic diarrhea that drinkers of sound cider enjoyed during the cholera epidemic in Somersetshire during 1848-1849. cider is neither acid nor sweet.

In an article entitled "Cider for India," which I published in the Medical Times and Gasette, April 27th 1867, at the suggestion of my friend, the late Dr. Robert Smith, occurs the following passage:—"In the early history of the Epidemiological Society, Mr Tucker drew attention to the remarkable fact that the cider drinkers of Somersetshire, during the epidemics of cholera in that county, were particularly immune from this disease. We can not only bear Mr. Tucker out in his statement, but, after twenty years' experience, add another fact of equal significance - viz., that the same people are free from gout also, and in this respect afford a strong contrast to their beer-drinking neighbours."

With regard to the freedom from gout observed among drinkers of sound cider, I will refer your readers to my remarks on this subject, and those of Dr. Woods, of Philadelphia, quoted by Sir Alfred Baring Garrod, in the second edition of his work on "Gout and Rheumatic Gout," 1863, p. 591. My article. "Cider for India," was written at the time when the regulation beverage of the In lian soldier was being discussed in the House of

Commons.

I am, Sir, yours truly, J. inuary 2nd, 1899. ALFRED HAVILAND.

HERNIA OF THE VERMIFORM APPENDIX.

SIE,-In the "Operating Theatres" of THE MEDICAL PRESS AND CIRCULAR of January 4th, a very interesting case of Hernia of the Vermiform Appendix from the practice of Mr. Battle, at St. Thomas's Hospital, is recorded.

The history given is a very typical one of hernia of the appendix in a femoral sac. This may occur in both the male as well as the female subject. It is not uncommon when it does occur for the appendix to become adherent at the neck of the sac, probably as the outcome of inflam-mation. The mouth of the peritoneal protrusion may thus be entirely blocked, and the communication with the abdominal cavity shut off. I have elsewhere (Trans. Path. Soc. Lond. vol. xlviii. p. 87) recorded such a case.

Hernia of the vermiform appendix alone in the sac is

undoubtedly a rare occurrence, but I venture to think that it is not so infrequent as is generally supposed. Moreover, when so herniated, I believe that, instead of inflammation being still more rare as a sequela, it is common for an appendicitis to ensue. Many of the cases recorded have been described as exhibiting the symptoms that have been considered to be indicative of a strangulated hernia, but if these be carefully looked into, they will very often, as in Mr Battle's case, show not the signs of intestinal obstruction but those of a local peritonitis, the consequence of a typical appendicitis, similar in every way to that which happens so frequently when the appendix is in its normal habitat.

I have in a paper (St. Barth. Hosp. Reports, vol. xxxii, p 93) collected seven instances where there was undoubted inflammation of an appendix in either a femoral or an inguinal sac, and in the same paper sixteen other cases in which, although strangulation was said to have been present, I cannot help thinking that the symptoms in evidence were really the result of inflammation rather

than of nipping of the tube.

Several other instances have been recorded since the

publication of my short paper.

In at least three cases a foreign body, in two a piece of bone, and in the other a pin, has been found in the protruded appendix, and may have been the chief cause of the inflammation.

If strangulation does occur the signs and symptoms produced are those rather of a partial enterocele, or of strangulation of Meckel's diverticulum than those of complete acute intestinal obstruction.

I am, Sir, yours truly,
W. McAdam Eccles.

Harley Street, W., January 5th, 1899.

CHLOROFORM AND ADENOIDS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

-The case of death from chloroform narcosis reported in your issue December 28th, 1898, like every previous death under an anæsthetic reported, confirms the truth enunciated by Snow fifty years ago, that unless the administrator of chloroform knows, at least approximately, the percentage of vapour he gives with each inspiration, he is a dangerous administrator, and should be held responsible for his imprudent action in taking upon himself the duty of administering a potent agent, of which, according to Snow, the undoubted highest authority on the action and safe administration of chloroform, 1 minim in the respired air, equal to 4.6 per cent of vapour, may cause sudden death, and 2 minims, equal to 9.2 per cent.; and 3 minims, equal to 13.8 per cent. of vapour, cause death with absolute certainty by paralysis of the heart, from which, according to this

observer, recovery is impossible.

Snow has shown, and Dr. Waller recently confirmed his results, that in a child æt. 6, the slow and regular progressive administration of from 0.23 per cent., and not exceeding 15 per cent., of chloroform vapour, suffices to produce deep yet safe anæsthesia, and 10 minim doses are sufficient to maintain the anæsthesia once in-

duced without risk to the subject.

Last October it was my lot to witness two cases of Snow's systematic method of chloroform administration. Female, æt. 3 years. Opening and scraping a suppurating gland in neck; under in four minutes; 42 minims of chloroform used in 17 minutes; average 2.5 minims per minute, equal to 0.12 per cent. of chloroform vapour. 2. A very nervous boy, æt. 14 years. Removing adenoid growths; under in about 8 or 9 minutes; 11 drachms of chloroform used in 25 minutes; an average of 3.6 minims per minute, equal to 018 per cent. of vapour in the vapoured air.

Neither of them was an ideal patient. They both resisted inhalation, especially the boy, who persistently held his breath. Their breathing was a series of spasmodic gasps. Much care was consequently needed to prevent the inhalation of an overdose. The chloroform was, therefore, given continuously in about $\frac{1}{10}$ or $\frac{1}{10}$ minims, and never more than 3 minim doses, until perfect anæsthesia was obtained. In these cases nearly one-half of the amount of chloroform used was wasted, for each dose meeting expiration is blown into the room. No sickness and no ill effect followed the inhalation.

I am, Sir, yours truly,
A DISCIPLE OF SNOW.

London, January 6th, 1899.

THE DISTRIBUTION OF THE PRINCE OF WALES'S HOSPITAL FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Those responsible for the financial condition of the Metropolitan hospitals will thank you for the public spirited manner in which you have exposed the fallacious

and partial basis of the awards of this fund.

In a letter to the daily press I took the position that many hospitals to whom awards were made are loaded with such conditions as to leave them "no better off than before." The editor of the Hospital for the current week remarks that my "statements and figures are equally inaccurate and unreliable." Permit me to quote for instances from two general and two special hospitals, which have received grants, to show that my statements are both accurate and trustworthy. I will do so in the form of a table, the figures being taken from "Burdett's Hospitals and Charities for 1898."

Name of Hospital.	Award.	Condition.	Cost per Bed per Annum.	Total Cost.	Deficit.
	£		£ s. d	. £	£
Great Northern Central	750	to open 15 beds	70 0 0	1,050	300
perance	500	,, 12 beds	95 0 0	1,140	640
City of London Chest N. London Con-	1,000	" 15 beds	90 0 0	1,350	350
sumption	1,000	,, 15 beds	87 0	1,305	305

Thus these four hospitals have to find nearly half as much again as the amount of their award in order to fulfil the condition of its bestowal.

I am, Sir, yours truly,

A HOSPITAL SECRETARY.

January 7th, 1899.

Obituary.

DR. EDMUND DAVY, OF DUBLIN.

WE much regret to report the death of Dr. Edmund William Davy, which took place on the 4th inst. at his residence at Rathgar, he being then aged 72. Dr. Davy was son of Edmund Davy, F.R.S., and an immediate descendant of the great Sir Humphry Davy. He was himself a distinguished chemist, and held the professorship of Chemistry in the Carmichael College, and that of Medical Jurisprudence in the College of Surgeons, Ireland, for many years, having been also the usual adviser of the Government in medico-legal cases. He was a kindly gentleman, and greatly esteemed for both his professional and his social qualities.

SIR JAMES MOUAT, K.C.B., M.D.

The death is announced of Sir James Mouat, K.C.B., V.C., honorary surgeon to the Queen, who died on Wednesday last at his residence, Palace Gardens Terrace, Kensington. He was born in 1815, studied at University College, and was admitted a member of the Royal College of Surgeons in 1837, and a Fellow in 1852. He entered the medical department of the Army as assistant surgeon in 1838, and after nearly forty years' active service, retired in 1876. Sir James Mouat was surgeon to the 6th Dragoon Guards, and in the Crimea had medical charge of the general field hospital of the 3rd Division until the fall of Sebastopol. He was awarded the Victoria Cross "for having voluntarily proceeded to the assistance of Lieutenant-Colonel Morris, of the 17th Lancers, who was lying dangerously wounded in an exposed situation after the retreat of the light cavalry at

the battle of Balaclava, October 25th, 1854, and having dressed that officer's wounds in the presence of the enemy."

SURGEON-GENERAL STANHOPE BRUCE.

WE regret to announce the death, at the age of 68, of Surgeon General Stanhope Bruce, on the 2nd inst., at his residence in Ealing. Deceased, who was the son of the late Colonel Louis Bruce, was admitted a member of the Royal College of Surgeons, England, in 1853, and entered the Indian Medical Service. He was actively engaged both before and during the Indian Mutiny in 1858. In 1880 he was engaged as Brigade-Surgeon in the Afghan War. He subsequently acted as Principal Medical Officer of the Second Division Kandahar Field Force, and later of the Afghanistan Field Force. His distinguished services were recognised by various medals. In 1887 General Bruce showed symptoms of bulbar paralysis, and retired in consequence.

Laboratory Aotes.

AËRATED TABLE WATERS.

THE improvements in the manufacture of plant for making aërated waters has led to a great increase in the production, both on a large scale and at local factories. It is fairly certain that a considerable part of this increase is due to the impression that such waters are safer than ordinary water; and, indeed, the reputation in this respect of the acrated waters from some districts has led to a large demand for them in even distant parts of the kingdom. The general feeling that aerated waters are safer than non-aërated is correct to this waters are safer than non-aerated is correct to this extent, that the much smaller supply required by an aërated water factory can be provided under precautions which are never taken with the much larger volume of a public supply intended for all purposes. In recognising this advantage, however, it must be clearly remembered that the manipulation involved in bottling aërated waters introduces an element of risk which does not occur in the public supply. A case in point, which occurred recently, was that of a manufacturer who, becoming unwilling to use a polluted well for manufacturing aerated waters, proposed to do so for washing out the bottles, a course which would have been entirely ncompatible with the purity of the water and was, in fact, abandoned on the advice of the analyst. Reputations for purity, on the other hand, have over and over again been shown to be entirely untrustworthy. illustration of this it may be mentioned that in the town of Maidstone there was a thriving industry of old standing in mineral waters, based on a reputation for purity; and this firm continued to export their products to all parts of the kingdom until the actual outbreak of the great epidemic.

We therefore come to the conclusion that it is desirable for the information of our readers to put forward some authentic and trustworthy information as to some of the brands most before the public. Our purpose is rather to assist those who desire the protection to which they are entitled than to criticise the manufacturers who do not give it, and our list will therefore refer more particularly to brands of the higher quality. The liability of aërated waters to convey infective disease has been thoroughly recognised for many years. The presence of carbonic acid in water, if it exercises any disinfectant effect, does so only after the lapse of considerable periods of time, and cannot be taken into serious account as a means of affording protection to the public. The results which we are about to publish are intended to indicate rather the natural character of the water which is used in the brands under examination than the precise merit of the fluished product. It cannot be too strongly recognised that the first line of defence against infection is the purity of the water supply. The purity is in almost all cases liable by accident to be impaired, and the demand for the adoption of uniform and trustworthy artificial means of bacterial purification, such as Pasteur filtration, has been increasing, and, in our opinion, ought to increase until

such means are universally adopted. In this way the public will obtain, and indeed has already begun to obtain, a second line of defence, and when it is uniformly adopted the impression that acrated waters are usually safer than the waters of a town supply will, for the time being, be justified. Our present figures bear on the first line of defence; and as the purity of a water supply, though not lying in the chemical composition of the water, is best indicated by it, we confine ourselves to the results of chemical analysis.

of chemical analysis.

"Mineral waters" are occasionally examined by public analysts under the Sale of Food and Drugs Act.

We are only able to find records for one year—namely, 1893, in which 168 samples were examined and 32, or 19 per cent were adversely reported on.

Unfortunately there does not seem to be any published record giving the reasons in all cases for their condemnation, the report only stating that in some cases lead was detected in small quantities.

"CAMWAL" SODA WATER.

The Chemists Aerated Mineral Waters Association, Limited, have factories in different parts of the country (London, Manchester, Birmingham, Bristol, Harrogate, and Mitcham) at which they prepare mineral waters. The samples we have examined were prepared from the "New River" water. Our analyses also included samples of the latter.

Label .- Camwal Soda Water.

From the results given above we conclude that in all cases the water employed in manufacture and the finished products are of high organic purity, and free from any trace of metallic contamination.

Medical Aews.

The Gresham Lectures.

DR E. SYMES THOMPSON, Gresham Professor of Medicine, will deliver a course of lectures in Gresham College, Basinghall Street, London, on the evenings of January 17th, 18th, 19th, and 20th, 1899, at six o'clock, the subject being "Preventive Medicine." These lectures are entirely free to the public.

Vital Statistics.

THE deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 19:1 per 1,000 of their aggregate population which is estimated at 11,218,378 persons in the middle of the year 1898.

Birkenhead 15, Birmingham 20, Blackburn 23, Bolton 23, Bradford 17, Brighton 18, Bristol 16, Burnley 16, Cardiff 14, Croydon 12, Derby 16, Gateshead 24, Halifax 14, Huddersfield 13, Hull 19, Leeds 18, Leicester 15, Liverpool 23, London 18, Manchester 23, Newcastleon-Tyne 21, Norwich 19, Nottingham 17, Oldham 23, Plymouth 22, Portsmouth 16, Preston 19, Salford 17, Sheffield 19, Sunderland 19, Swansea 21, West Ham 19, Wolver-hampton 24. The highest annual deathrates per 1,000 living, as measured by last week's morin Nottingham; from whooping cough, 1:1 in Oldham and 1:3 in Preston; from "fever," 10 in Derby and in Gateshead, and 13 in Bolton; and from diarrhea, 10 in Derby, and 18 in Wolverhampton. In none of the Derby, and 18 in wolvernampton. In none of the large towns did the death-rate from scarlet fever reach 10 per 1,000. The 106 deaths from diphtheria included 47 in London, 8 in West Ham, 7 in Sheffield, 6 in Birmingham, 5 in Swansea, 5 in Liverpool, 4 in Leicester, 4 in Leeds, 3 in Cardiff, 3 in Mauchester, and 3 in Blackburn. No death from small-pox was registered in converted the United Kingdom. in any part of the United Kingdom.

The Mortality of Foreign Cities.

The following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Calcutta 26, Bombay 42, Madras 42, Paris 7, Brussels 16, Amsterdam 14, Rotterdam 16, The Hague 16, Copenhagen 18, Stockholm 15, Christiania 13, 16 Lingue 16, Copenhagen 18, Stockholm 15, Christiania 13, Sreslau 14, Munich 20, Vienna 19, Prague 27, Rome 15, Turin (10, days) 15, Venice 18, New York (including Brooklyn) 17, Philadelphia 18.

The Hospital Sunday Pund.

THE collections made in London for the Hospital Sunday Fund last year says the St. James's Gazette, show a falling off from those made in 1897. The contributions in church are less by £529, while the chapel contributions have decreased by £313 The church now finds nearly four-fifths of the whole amount collected-namely, £29,106 out of a total of £36,513.

Mr. H. Rider Haggard and the Jenner Society.

AT the last meeting of the Executive Committee of the Jenner Society held in Gloucester, the following resolu-tion was passed unanimously:—"The members of the Executive Committee of the Jenner Society desire to express their appeciation of the recognition of the work of the Society by Mr. Rider Haggard, in the dedication to its members of his powerful story, 'Dr. Therne.' They also desire to assure Mr. Rider Haggard of their warm sympathy with his just and vigorous protest against the dangerous agitation carried on against vaccination, by which many thousands of persons have been misled, and have been induced to deprive their children of the only certain protection against a virulent and fatal disease. The committee congratulate Mr. Haggard upon his uncompromising exposure of this evil, and trust his book may have a large circulation, as being calculated to lead a considerable section of the public, who cannot be otherwise interested in the subject, to give serious consideration to a matter of urgent and overwhelming importance, affecting, as it does, the health and lives of multitudes of hapless children who may be exposed to the infection of smallpox, without the protection afforded by vaccination."

University of London.

THE following candidates passed the recent B.S. Examination for Honours.—Surgery.

First Class.—John Preston Maxwell, Gold Medal, St. Bartholomew's Hospital.
Second Class.—Thomas Variey Cunliffe, Owens College and Manchester Royal Infirmary: Domald John Munro, Guy's Hospital.
Third Class.—Winifred Secretan Patch, B.Sc., Royal Free Hospital and London School of Medicine for Women.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are par ticularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves ' Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

A CURIOUS WILL

A CURIOUS WILL.

The will of the late vicar of Stapleton (Cambridgeshire), which was recently admitted to probate, contains the following curious clause: "I will that after my decease and within six hours of my burial a certificate as follows be given in writing to the person in charge by two members of the Royal College of Surgeons in England." The following certificate in the form prenared by the testator is attached to the will:—"We Joseph Griffiths and John Gay, duly qualified surgeons, and who are not in business partnership, certify that we have severed the right leg above the knee of a corpse shown us as that of the late Charles Henry Thomas Wyer Daw, and which we believe so to be.—Joseph Griffiths, M.R.C.S. Eng.; John day, M.R.C.S. Fing., 1.R.C.P. October 25th, 1888." The will continues: "I will that thee guine is be paid to each surgeon, but they may take the severed limb at the price of three guineas as part payment if they so chouse: the corpse will then pack in an ordinary coffin with or without the reverest limb. I will that if the severing of the right leg be omitted and not certified by two surge ons that the whole of thin my will be cancelled and of no effect, except the provision for my daughter Annela Mary Daw, which shall then be administered by the High Court of Justice, and shall include all available property at my disposel." The gross value of the estate has been estimated at £4.230.

We doubt very much whether any member of the College of Surgeons would willingly accept a dead clergyman's leg in lieu of three guiness. No information is forthcoming as to whether these instructions were complied with, but as probate has issued, we may infer that the two gentlemen mentioned therein have been paid their honoraria.

M. K.—The matter is under consideration and will be dealt with

M. K.-The matter is under consideration, and will be dealt with in due course.

EXOR.—We do not pretend that our opinion has force of law. You asked for it, and it is for you to decide whether or not to act on it. The metter is of too exclusively private interest to justify cur dealing with it editorially.

DR. OGILVIE.-Your MS. has been received, and will be dealt with as requested.

with as requested.

C. A. ECCLES (Priffield).—A correspondent under this signature has favoured us with her views on "The Dietetic Value of Plum Pudding," which appeared in a recent number of this journal, and was quoted in hundreds of newspapers. As a vegetarian she avers that although they (vegetarians) would not outrage their humane feelings to procure the necessary suet, which involves "the life of a highly organised and sentient beast," yet "there are many vegetable oils and fats that may and do more wholesomely take its place." In reference to the use of eggs she writes:—"It is usually the hyper sensitive reverence for life of those who love to cavil at vegetarianism, not veg-tarians themselves, who would wish to bar the ggs."

Meetings of the Societies and Tectures.

WEDNESDAY, JANUARY 11TH.

DERMATOLOGICAL FOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m. Clinical Demonstration.

SOUTH-WEST LOWDON MEDICAL SOCIETY (Town Hall, Wandsworth, S.W.).—8.80 p.m. Dr. J. B. Ball: Paroxysmal Sneezing and Allied Affections, their Causes and Treatment.

HUNTERIAN SOCIETY.—8.30 p.m. Pathological Meeting. Specimens will be shown by Dr. Uliver, Mr. Targett, Dr. F. J. Smith, and other Fellows of the Society.

THURSDAY, JANUARY 12TH.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.)— 30 p.m. Annual Meeting for the Election of Officers. Presi-8.30 p.m. Ann dent's Address.

SOCIETY FOR THE STUDY OF INEBRIETY.—Quarterly Meeting (Rooms of the Medical Society of London) at 4 o'clock. Paper: The Temperance Fallacy. A rejoinder to Dr. Norman Kerr, by Archdall Reid, M.B. Southsea.

FRIDAY, JANUARY 18TH.

SCHOOL DENTISTS' SOCIETY (Medical Society's Rooms, Chandos Street, Cavendish Square, W.). 7 p.m. Casual Communications, Paper:—Mr. W. T. Elliott (Birmingham): Classification of the Ages of Children for the purpose of Statistical Observation. Followed by Liscussion.

Followed by Liscussion.

CLINICAL SOCIETY OF LONDON.—8.30 p.m., Clinical Evenling. The following cases will be shown:—Mr. J. Hutchinson. jun. S. Localised Myositis Ossificans from Injury.—Dr. Crawfurd: Enlarged Spleen with Thrill and Bruit.—Mr. Curtis: Anterior Displacement of Tuberculous Carpus with Formation of a False Joint (skiagrams and stereoscopic photographs by Dr. Mickenzie Davidson).—Dr. J. S. Richards: Pemphigus of the Mouth. Pharynx, Larynx, and Skin.—Dr. Batten: Progressive Muscular Atrophy after Measles.—Mr. Kellock: Two Cases of Complete Hypospadias with Cleft Scrotum.—Dr. Perkins: (1) A Case of Progressive Muscular Atrophy of Unusual Distribution; (2) A Case of Muscular

Atrophy (Myopathic).—Wr. L. A. Junn: Charcot's Disease of the Hip. And other cases. Patients will be in attendance at 8 p.m. ROYAL ACADEMY OF MUDICINE IN IRELAND.—SECTION OF PATHOLOGY.—1. Dr. Knott: Pathological Femora and Tible: 2. Mr. H. G. Croly: (a) Tumour of I eft Ovary, (b) Specific Fungus of Testis, (c) Carious Os Calcis, (d) Tumour of Breast of eighteen years standing, (e) Portion of Fractured Superior Maxilla 3. The Secretary: Note on the Agglutinability of Different Races of the Typhoid Bacillus. 4. Dr. Conolly Norman: Case of Peritoneal Tomour. 5. Dr. Coleman: (a) Gio-sarcoma of Cerebral Femisphere, (b) Tubercular Tumour of Cerebellum. (c) Abscess of Cerebellum.

Vacancies.

County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary commencing at £100 per annum, with furnished apartments, board, attendance, and washing. Dorset County Hospital. Dorchester.—House Surgeon for twelve months, unmarried. Salary £80 To reside and board in the

hospital. Salary 200 To reside and board in the hospital. General Hospital, Nottingham.—House Physician for two years. Salary £100, ri-ring £10 a year to £120, with board, lodging, and washing.

Newcastle-on-Tyne Dispensary.—Visiting Medical Assistant for at least one year. Salary £120 for the first year and £150 afterwards.

wards.
Plaistow, St. Mary's Children's Hospital.— Senior Resident
Medical Officer for one year. Salary £30 per annum, with
residence in the hospital, board, and washing.
Tynemouth Victoria Jubilee Infirmary, North Shields.—Resident
House Surgeon. Salary £35 per annum, with board, lodgings,
and washing. Applications to the Secretary, 43, Howard
Street, North Shields.

Appointments.

BARTER, WILLIAM, M.D., M.Ch., Medical Officer for the employes of the London District, Great Central Railway.

BRISCOR, JOHN CHARLTON, M.R.C.S., L.R.C.P. Lond., House Physician for King's College Hospital, London.

CAMPKIN, P. 8., L.D.S.Eng., Dental House Surgeon for Guy's Hospital London.

Beiscoe, John Charlton, M.R.C.S., L.R.C.P. Lond., House Physician for King's College Hospital, London.
Campkin, P. S., L.D.S.Eng., Dental House Surgeon for Guy's Hospital, London.
Colls, Percy Cooper. M.R.C.S., L.R.C.P.Lond., House Surgeon for King's College Hospital, London.
Dickinson, Wm. Lee, M.D.Camb., Lecturer in Toxicology and Forensic Medicine to St. George's Hospital Medical School, Bden, Thomas Watts, M.D.Bdin., M.R.C.P.Lond., an Assistant Obtebric Physician for the Charing Cross Hospital, London. Gerraves, Frank, M.R.C.S., L.R.C.P., House Surgeon for the Derbyshire Royal Infirmary, Derby.
Hennessy, D., L.R.C.P., L.R.C.S., Edin., L.F.P.S.Glasg., Medical Officer, pro tem., for the Clonakilty Workhouse.
Levick, Percy, B.A., M.B., B.C.Cautab., House Surgeon for King's College Hospital, London.
Lewis, Collon Taylor. M.R.C.S., L.R.C.P.Lond., House Accoucheur for King's College Hospital, London.
Levis, H. D.S. Eng., Dental House Surgeon for Guy's Hospital, London.
Mason, B. N., L.D.S. Eng., Dental House Surgeon for Guy's Hospital, London.
Osle Cyralt, M.B.Oxon., M.R.C.P.Lond., 1 ecturer in Practical Medical School.
Owen, Isambard, M.D., F.R.C.P.Lond., Joint Lecturer (with Dr. Rwat') in Systematic Medicine to St. George's Hospital Medical School.
Bobberts, Gerroel Augustus, M.R.C.S., L.R.C.P.Lond., Assistant House Physician for King's College Respital London.

ROBERTS, GEORGE AUGUSTUS, M.R.C.S., L.R.C.P.Lond., Assistant House Physician for King's College Hospital. London.

St. John, Winstan St. Andrew, M.R.C.S., L.R.C.P., House Physician for the Derbyshire Royal Infirmary, Derby.

SAUNDERS, LEONARD DIMOCK. M.R.C.S., L.R.C.P., Iond., Assistant House Accoucheur for King's College Hospital, London.

Marriages.

BATEMAN—HIGHAM—On Jan. 3rd, at 8t. Paul's Church, Bath, R. W. Bateman, Durham House, Bournemouth, L.R.C.P.Lond., M.R.C.S. King., L.S.A., to isabella Higham, widow of the late William H. Higham Brereton, Dean Park Bournemouth.

MADGE—PAUL—On Jan. 4th, at 8t. George's, Hanover Square.
London, Edward Bouglas Madge, M.R.C.S., L.R.C.P., L.S.A., of Nottlingham Place, W. to Annie Chaston Faul, eldeat daughter of J. J. 1 awson Paul, J.P., Eston Grove, Norwich.

HYNES—KETILEWELL—On Jan. 3rd. at 8t. Paul's Church, Bedford, Ernest Jermyn Hynes, M.R.C.S., L.R.C.P., of Stcck ton-on-Tees Hespital, to Florence Maud, daughter of Lieut.-Col. G. Roche, Kettlewell, late Bengal Army.

WILLIS—THEING—On Jan 5th, at 8t. Peter's Church, Bournemouth, Cyril Hamer Willis, M.R.C.P., L.R.C.P., lond., younger son of the late M. M. Willis, of Beckenham, Kent. to Annie Bertha, youngest daughter of the late Robert Thring, of Winchester.

THE CONDUCT OF THE HEART

IN THE

FACE OF DIFFICULTIES. (a)

By Sir WM. BROADBENT. M.D., F.R.C.P.Lond., Consulting Physician to St. Mary's Hospital; Physician in Ordinary to H.R.H. the Prince of Wales.

I should like the Society to understand that I am in no way responsible for the title of this communication, but that I accepted it at your dictation. There are appeals more imperative than commands. Such was yours when, as an old pupil become president of this Society, you requested me to read a paper on the conduct of the heart in the face of difficulties. I was bound to obey, but I ventured to point out that the word "conduct" in this phrase might have two distinct meanings—the behaviour of the heart itself under difficulties, or the way in which it might be helped and guided through them by the physician, and to ask which of the two questions was to be discussed. You promptly answered "both." It is by your command, therefore, that a double entendre is inflicted upon the Society. In dictating the title you practically also decided the way in which the question was to be treated.

The difficulties which the heart has to face are sometimes of its own making, sometimes imposed upon it from outside. An over-distended stomach, for example, pushes up the diaphragm and presses upon the right ventricle; the heart is carried to one side or other of the chest by effusion into the pleural cavity, or more rarely is displaced by a mediastinal tumour or aneurism; or the flow of blood towards the right auricle may be impeded by pressure on the superior vena cava. Difficulties of another kind may arise from obstruction in the arterioles and capillaries—in the pulmonic circulation by emphysema or by acute affections of the lungs; in the systemic circulation by the numerous conditions which give rise to high arterial tension.

The heart adjusts itself to altered conditions in a wonderful fashion. It may be so much displaced by effusion into the left pleural cavity or by traction from a shrunken right lung that its beat is felt as far out as the right nipple and yet we can trace very little inefficiency in the functional action. Time, however, is an element in this accommodation. The same degree of displacement occurring suddenly as in pneumothorax, will be attended with severe dyspnœa and great disturbance of the action of the heart will be occasioned by sudden and capricious distension of the stomach.

The difficulties arising out of flatulent distension of the stomach or colon or intestinal canal generally will require some attention, since they are the cause of most of the functional derangements to which the heart is subject, and give rise to the heart complaints which occasion in the aggregate perhaps more suffering than does actual heart disease. The

(a) Paper read before the Medical Society of London, January 9th, 1899.

heart often tolerates a considerable degree of upward pressure of the diaphragm, and it is not uncommon to meet with stomach resonance as high as the 5th space, and to find the apex beat displaced upwards and outwards to the 4th space and outside the nipple line without conspicuous symptoms. But the heart behaves very differently in different subjects in the presence of flatulent distension of the stomach. It partakes of the general constitutional condition of the individual; in the strong, therefore, it is virorous, in the weak it cannot be anything but weak. Then the heart has very special relations with the nervous system; it reflects every emotion, beats high with courage, is palsied by fear, throbs rapidly and violently with excitement, acts feebly under nervous depression, but it is not only through the cerebro-spinal system that the heart is influenced, it is in immediate relation with the vaso-motor nervous apparatus, and in a scarcely less degree with the sympathetic system generally. Normally afferent impulses are brought from the viscera to the central nervous system by means of which their blood supply is regulated, and their functional activity governed. These afferent impulses when perverted by functional derangement or disease may become serious disturbing influences. But the nervous sys-tem in a large and increasing proportion of people is unduly sensitive and excessively mobile, and the reactions to influences of every kind are exaggerated. A little emotional excitement gives rise to palpita-tion, a piece of bad news or the bang of a door seems to stop the heart altogether. There is in such subjects no form or degree of cardiac disturbance which may not be caused by indigestion, scarcely any symptom of cardiac disease which may not be simulated. Add a touch of hysteria on the lookout for symptoms and for someone to give ear to the relation of the unparalleled agonies of the sufferer, and the difficulties of the heart, and it may be added of dealing with them, are complete.

It is of course of the greatest importance that we should be able to distinguish these functional affections of the heart from troubles due to organic disease, and this is especially the case where there is severe pain in the cardiac region. The absence of physical signs of valvular or structural change will be a help, but murmurs may be present at one or more of the orifices during palpitation when there is no valvular affection, and there may be actual mitral or tricuspid incompetence when all the symptoms are really of neurotic or dyspeptic origin.

Angina pectoris is one of the cardiac affections which may be closely simulated by the effects of dilatation or functional derangement of the stomach. The first question to be put in a case of cardiac pain of anginoid character is "As to the circumstances under which it comes on?" Whether as an effect of exertion or during repose? The earlier attacks of true angina are practically always provoked by exertion, while spurious angina is specially liable to come on during repose. It is true that angina when established may come on in the night, or may be induced by the act of undressing and the contact of cold sheets, but there will be a history of attacks during exertion. Pain and a sense of suffocation

may also be brought on by the pressure of the abdominal viscera reinforcing that of a distended stomach on lying down whether the heart is diseased or sound, and a weak heart may actually be brought to a standstill in this way. Speaking generally, angina pectoris in a woman is always spurious, and the more minute and protracted and eloquent the description of the pain the more certain may one be of the conclusion. Again, when palpitation or irregular action of the heart, or intermission of the pulse, or pain in the cardiac region, or a sense of oppression follows certain meals at a given interval, or comes on at a certain hour during the night, there need be little hesitation in attributing the disturbance, whatever it may be, to indigestion in one or other of its forms. Nightmare from indigestion is not a bad imitation of true angina. So also if any cardiac symptom or pain can be walked off, it may usually be set down as functional, and due to some outside disturbing influence or to nervous irritability. The same may generally be said of intermission of the pulse, of which the patient is conscious, and, though with less confidence, of irregularity of the heart's action-if the patient feels it the irregularity is usually temporary, and not the effect of organic

In these functional affections, it is not the heart which is to blame; it is more sinned against than sinning, and if its difficulties are removed there will be nothing to find fault with in its conduct. difficulties are, as has been said, the state of the nervous system, on the one hand, and of the digestion on the other, and according as the neurotic or the dyspeptic element predominates will be the treatment required. No details need be entered into, but one observation may be Patients suffering from these functional derangements of the heart usually make them a pretext for avoiding exercise and fresh air and often for taking stimulants or drugs whereas exercise and fresh air are what he or she most needs. The best way to prevent the expenditure of superfluous energy on the part of the heart in the form of palpitation is to give it a fair amount of legitimate physiological work to do and to relieve one attack of pulpitation or faintness by alcohol is to invite another, while the terrible danger of drifting into alcoholism is incurred.

One of the most common difficulties with which the heart has to contend is high arterial tension, or rather the obstruction to the onward movement of the blood in the capillaries and arterioles which is the cause of the high pressure in the arteries. While dyspeptic troubles and other reflex sources of irritation give rise merely to functional affections of the heart, high arterial tension when persistent is a frequent cause of actual disease. The resistance in the peripheral circulation has to be overcome and the heart rises to the occasion. It puts forth the increased energy required and in doing so becomes hypertrophied. Hypertrophy is not disease, though sometimes the heaving impulse and powerful throb of the apex are complained of by the patient and looked upon with suspicion by the medical man, but the development of additional muscular fibre is accompanied by the development of increased connective tissue, and when in the decline of life the nutrition

of the more highly organised structures is no longer vigorous, the fibroid element may gradually predominate over the muscular, or fatty degeneration may take place.

But the valves may suffer before the muscular walls. Where greater force is required to propel the blood into the aorta there is greater strain upon the mitral valves during systole, and a more violent recoil upon the semilunar aortic valves during diastole. This gives rise to chronic inflammation of the valves, with thickening and contraction, and,

in the long run, insufficiency.

It was necessary to mention high arterial tension on account of its frequency and importance as a source of cardiac difficulty, but I have dealt with it so often and so recently that I will forbear from further dwelling upon it on the present occasion, only remarking that the recognition of unduly high pressure in the arteries affords one of the most valuable indications for treatment in a great variety of conditions.

I am afraid it often escapes recognition, and sometimes digitalis is given for the relief of the cardiac discomfort which may attend it. This is like knocking the head against a stone wall, for digitalis not only acts on the heart, but tightens up the vessels, and so increases the obstruction already too great.

Coming now to the serious difficulties to which the

Coming now to the serious difficulties to which the heart is exposed by reason of damage to one or other of its valves, we discover, say, a systolic murmur at the apex or at the right second intercostal space, indicative of leakage of the mitral valve or of interference with the blood current at the aortic orifice. What are we to do? Frighten the patient out of his life or out of his peace of mind? Condemn him at once to live on one floor, and forbid him exercise and excitement and all that makes life tolerable, and give digitalis? Certainly not. Or shall we ignore the murmur on the chance that it may not be serious, which is a not uncommon proceeding when a medical man has predicted sudden death once or twice, and found the patient to go on living for ten or twenty years? This would be equally unreasonable.

The first thing to be done is to ascertain what the murmur really means; whether, when it is mitral, there is much or little regurgitation, or, if aortic, whether it signifies mere roughness or actual construction. Numerous considerations enter into the determination of these questions, of which we need specify only those arising out of the conduct of the heart. If, in the case of mitral incompetence, there is any considerable reflux into the left auricle, the first effect will be damming back of the blood entering it by the pulmonary veins, and the obstruction thus created will make itself felt in the pulmonary artery, raising the blood pressure within it. There is no branch of the pulmonary partery or which we can place our force one. monary artery on which we can place our finger or a sphymograph but the high pressure is at once accused by accentuation of the pulmonic second sound. If the circulation is to be maintained under these circumstances something must be done to overcome the obstruction in the pulmonary circulation and neutralise the mitral reflux. This can only be by increase in the capacity and strength of the right ventricle. The right ventricle accordingly becomes dilated and hypertrophied, and the dilatation and hypertrophy which we call compensatory, be-come for us the measure of the regurgitation. This is the conduct of the heart in the face of this particular difficulty, and we learn from the amount of compensatory change required to neutralise the effects of the valvular lesion whether the lesion is severe or slight; our conduct then will be guided by the degree of efficiency of the compensation. When there is no appreciable hypertrophy of the right ventricle or marked accentuation of the pulmonic second sound, and the patient has no heart-symptoms, the murmur means nothing, and there is no need to interfere in any way with the patient's mode of life even if this include hunting or climbing, or swimming, or cricket. I should draw the line of football or training for races of any kind.

If with marked hypertrophy and dilatation there is still no breathlessness on ordinary exertion or other circulatory symptoms the regurgitation is considerable, but it is neutralised by the compensatory changes. We are not called upon to do anything but the patient must be warned that the compensa-

Digitized by GOOGLE

tion may easily be broken down, and that a single imprudent act of violent or sustained exertion may do

irreparable injury.

Cardiac symptoms, such as breathlessness on slight provocation, show that the compensation is inadequate, and it is only by great carefulness that the serious effects of the valvular lesion can be put off. Let us suppose that we have the heart landed in extreme difficulties from incompetence of the mitral valves, the liver enlarged till its lower border crosses the abdomen at the level of the umbilious, the veins of the neck distended and pulsating, the face and lips livid, the lungs congested, the legs dropsical, the ur ne scanty, turbid, and albuminous, the patient gasping for breath and unable to lie down. It is in mitral incompetence that digitalis and such like remedies find their opportunity. But first the right side of the heart must be relieved from the over distension which is paralysing its efforts. Unless this is done the digitalis may simply help the straining ventricle in the work of self-destruction. The nearest approach to a modern therapeutic miracle is seen on bleeding in a good case of this kind. When I say a good case I mean one in which the onset of the seve e symptoms has been sudden under the influence of some adequate exciting cause such as over exertion or chill in a fairly robust subject with a powerful right ventricle. The venesection must be followed up by a good calomel purge, two or three grains of calomel with, say, five of colocynth and hyoscyamus, and perhaps a dose of white mixture. Bleeding, however, is too heroic a method for these degenerate days, and it is not always easy to say whether it is really demanded. A good alternative is 6, 8, or a dozen leeches over the enlarged liver followed up of course by the calomel purge. In less severe cases we may content ourselves with the mercurial aperient.

The right heart having been relieved, digitalis may be given with excellent effect in different combinations, according to the condition, with nux vomica and ammonia and perhaps ether, or with acetate of iron and potash. If the ordema is considerable it should be drained off by Southey's tubes, and any pleural effosion should be withdrawn by aspiration at

an early stage.

Mitral incompetence will serve as an illustration of the difficulties imposed upon the heart by disease of the valves. They differ in the different valvular affections, and the heart responds in a special way for each one. It is unnecessary to go into details with regard to all of them and the time at my disposal would be quite insufficient. The principle which I wish to emphasise is that when the heart is in difficulties, we can generally do more for the relief of the patient indirectly by removing the difficulties than directly by aiding it to overcome them. This is the case whether the disturbing influence is external to the heart, as, for example, a dilated stomach, or distended colon, or resistance in the peripheral circulation, or is a secondary effect of disease of the heart itself, as illustrated by over-distension of the right ventricle; or, to take another instance, if the heart is in a state of fatty degeneration, it is useless to give cardiac tonics; but its work can be diminished by keeping down the arterial tension, and a fatal issue may be for a time averted by preventing distension or dilatation of the stomach. Such illustrations might be multiplied indefinitely.

When, therefore, we are considering the treatment of cardiac disease or disturbance, the first question to engage the attention is how we can relieve the labouring or harassed heart by the removal of some condition which is causing or aggravating the difficulties with which it is contending. In doing this we often put an end to the symptoms which have given rise to suffering and anxiety, and in all cases we

make the action of digitalis or other cardiac tonics more efficacious.

INFLUENCE OF THE MILK SUPPLY

ON THE

SPREAD OF TUBERCULOSIS.

Based upon an Investigation of Sixteen Milk Supplies in Cambridge.

By A. A. KANTHACK, M.A., M.D., F.R.C.P., Late Fellow of Ring's College, and Professor of Pathology in the University of Cambridge.

AND

E. SYDNEY ST. B. SLADEN, M.A., B.C., M.D., Cambridge.

LAST April the late Professor Kanthack suggested, as a subject for research, the study of the effect upon the spread of tuberculosis produced by the various milk supplies to the different colleges in Cambridge. He very kindly offered his assistance. It is, therefore, under his guidance, and with his help and advice, that the following record of results has been compiled

This paper is limited to a narrative of our joint work—the investigation of the tuberculous lesions and the presence of the tubercle bacillus found in guines-pigs as the result of inoculation of milk, no notice being taken of other points of int-rest outside the immediate subject. This is due to the fact that the present article, though complete in itself, is only a preliminary paper. We are now carrying out a further and exhaustive investigation on the milk supplies in Cambridge, leading, we hope, to the near future of buying milk which comes from cows certified to be free from tuberculosis.

Experience and observation have convinced us that infantile tuberculosis is by no means uncommon in Cambridge; and since the danger now generally recognised abroad, of spreading tuberculosis by milk, is gradually being appreciated in this country, all that is needed is to rouse people at home to the consciousness of this danger and make them understand that it is their duty to insist on being supplied with milk free from tuberculous infective material.

Similar investigations have been made in other parts of the world, and they are already bearing fruit. We may thus mention the work of Professor Bang of Copenhagen, of Professor Delépine in Manchester, and the well-known researches of the Royal Commission.

Professor Delépine's work has already induced the late Lord Vernon to follow the example set by the Danes and Germans, namely, to stamp out tuberculosis in his own herds. We hope that once the Colleges have recognised the true state of affairs they will insist on obtaining a pure milk supply, and will assist the dairymen in bringing about improved conditions. The manner in which this may be done will be discussed in the fuller report, which unfortunately has been delayed by Professor Kanthack's

The object of this paper is to set forth the evidence upon which the fuller report is mainly based. To collect such evidence is a matter of some difficulty, and, at any rate, requires a considerable amount of time and labour. It may be noted that Professor Kanthack saw every animal which was dissected, and in every instance the diagnosis was accepted and confirmed by him before it was placed on the records.

1. Method of Work.—Early in May, arrangements were made as regards collection of the milk and a regular supply of healthy guinea-pigs.

During the first three days only twelve guinea-pigs were inoculated, four each day; afterwards, when a routine method had been devised, the number was increased to six each day, and this number was adhered to throughout the remainder of the work.

It was decided to inoculate two guinea-pigs with each sample of milk, and to continue this for two successive days using fresh guinea-pigs each day, so that each separate supply was thus passed through six guinea-pigs: the only exception to this arrangement was H.'s supply, which was inoculated into four guinea-pigs, owing to forgetfulness on the part of one of the College porters to have the bottle left with him filled with milk.

· It was found more convenient to use the morning delivery of milk in place of that obtained in the afternoon, owing to the work sometimes occupying much time.

Thus, although more time was lost between collection and inoculation, still by putting off the staining of any cover glass preparations until after all the inoculations had been made, this loss of time was inconsiderable.

Some of the samples of milk were collected as early as 6 a.m., and as it was impossible to start work before 9 a.m., some time elapsed before the inoculations could be made, the greatest difference between the time of collection and inoculation being four hours, and the smallest being fifteen minutes; an average taken of all the experiments shows the difference to be just under two hours. This, however, is immaterial, since we are here dealing with the tubercle bacillus only.

2.—Method of Collection of the Milk.—(a) A glass stoppered bottle having been well washed, done up in paper and tied with string, was placed in the steriliser and sterilised half an hour at a temperature of

115 Centigrade.

(b) The bottle when cold was usu lly taken to a College (the permissi n of the College Authorities having been previously obtained) and left with the porter or at the kitchen some hours before the particular milkman arrived.

(c) In the presence of the milkman the bottle was opened and then filled by the milkman direct from his can: it was immediately shut again, done up in paper and tied with string; the milkman's name was then written on the paper covering the bottle.

Thus the milk, as it was received for examination at the Pathological Laboratory, was in exactly the same condition as that in which it was while in the milkman's can, the only difference being in respect of the time lansing between collection and examination.

the time lapsing between collection and examination. The milk was of course "mixed," i.e., derived from different cows. Later, it is intended to examine the milk from individual cows, in order to gain an idea as to how many cows proportionately are tuberculous. Here we are dealing with the question of the milk generally, and it is our intention to go no further in this paper than the investigation of the "mixed" milk of each supplier.

3. Method of Inoculation.—Previous to all inoculations all instruments and vessels had been sterilised by heat, and after each operation were at once placed in strong lysol solution, so that it was quite impossible that these could be held liable for any accidental infection with tubercle bacilli. A fresh syringe and needle, both carefully sterilised, were also employed for each separate sample of milk.

With the exception of two cases each inoculation was made into the right groin of a guinea-pig.

Two tubes of a Metzger centrifugal machine were filled up to the 10 c.c. mark with milk taken from each sample, these were then centrifugalis d for five minutes, the time being always accurately kept by reference to a clock placed just over the centrifugal-

ising machine. The machine was usually worked at the rate of 3,000 to 4,000 revolutions per minute.

The average yield of cream from 10 c.c. of milk after centrifugalisation was found to be 0.93 c.c. Later in this paper it was stated that 3 c.c. of the "creamy layer" were inoculated; that is to say, as much cream as possible was collected from each of the two glass tubes, the remainder being made up of the milk floating next to the cream.

The "sediment" refers to the deposit found at the bottom of the glass tube; to this part all solid particles should have been driven, but as will be noticed later this does not apply to all the tubercle bacilli when present in milk, some remain in the sediment, but a considerable number are carried up and remain in the creamy layers.

Two guinea-pigs were then inoculated, one with the creamy layer, another with the milk at the bottom of the glass tube.

The following is an example of the method employed for each sample of milk, being taken from notes recording the inoculations of the 67th and 68th guinea-pigs:

(1) Time of reception from dairyman, 4 p m.

(2) Time of centrifugalisation (two tubes each containing 10 c.c.), 4.30 p.m.

(3) Yield of cream after centrifugalisation from one tube, 0.25 c.c.

(4) (a) 3 c.c of creamy layer (taken from the two tubes) were inoculated into right groin of one guinea-pig. (Label I. 67 a.) Rough haired, fawn and white.

(b) 3 c.c. of sediment were inoculated into right groin of another guinea-pig (Label L. 68. b.) Black and fawn.

(5) Cover glass preparations were 'hen made from the sediment which, after allowing sufficient time for drying in the air, were stained by carbolised fuchsine and counter stained by methylene blue in the usual way in order to differentiate the tuber-le ba-illus from other bacilli.

On examination with the aid of a $\frac{1}{12}$ oil immersion the results were:—

(a) Co ci and diplococci, but only few in number.

(b) Tubercle bacilli (two present in one preparation)

The amount inoculated ranging from 15 c.c. to 3 c.c. was determined in accordance with the size of the guinea-pig, if of large size then 3 c.c. were used.

An average of all the quantities inoculated gives this result: 2.4 c.c. for the creamy layer, 2.1 c.c. for the sediment. In the guinea-pigs that died of tuberculosis the average amount inoculated was 2.28 for the creamy layer and 2.07 for the sediment.

4. Method of keeping Animals under Observation.—
For the first three days all the guinea-pigs inoculated on those days were kept in one cage, having celluloid labels fastened by lead wire round their necks (a contrivance Dr. L. Cobbett very kindly suggested).

Besides this means of recognition a detailed account of the colours and peculiarities of the guineapigs was made in case the labels should chance to get lost.

When the cage contained eighteen guinea-pigs, each group of six, i.e. each group of animals belonging to each particular dairy, was picked out, and placed in a separate cage, the labels being afterwards removed, and this method was adhered to to the end of the investigation.

The guinea-pigs were kept in the country under the best possible conditions and were examined twice a week. After having been under observation for several weeks, when any showed marked enlargement of the inguinal glands, these were killed by ether or chloroform.

5. Method of Examining the Guinea-pigs .- Each

guinea-pig after death was carefully opened and examined for any signs of tuberculosis. If any signs of tuberculosis were present they were noted and a general description written down. Cover-glass preparations were at once made, the part to be stained being taken from an abscess or a nodule in the spleen or a caseous lymphatic gland: these were stained for tubercle bacilli in warm carbol fuchsine, passed rapidly through HCl (1 in 4) decolorised in 70 per cent. of methylated spirit and counter-stained with methylene blue. Parts of the spleen, liver, lungs, and glands were then bottled in Müller's fluid, a label being placed on the bottle.

When hardened sufficiently, small portions were removed and embedded in paraffin. Four sets of sections were stained, two with hæmatein and eosin. and two others (as above) for tubercle bacilli.

In many cases several sets had to be cut and stained before positive results could be obtained. This is important because it is known that in milk. and especially in butter, pseudo-tubercle bacilli may occur which in the guinea-pigs produce lesions macroscopically resembling tubercle, but micro-scopically differing from the true tubercle, in that the histological elements of tubercle are absent. Cultures were not made from the various organs, since this is very laborious, difficult and uncertain; and the other tests taken altogether were sufficient to establish a correct diagnosis.

By microscopic examination, out of the 33 guineapigs suspected of having contracted tuberculosis, 10 were found to be not affected with tuberculosis, 23 showed typical histological tuberculous lesions, whilst in 16 of the 23 the tubercle bacillus was plainly

demonstrated.

Following the example of those who made experiments upon guinea-pigs for the Royal Commission on Tuberculosis and discarded from their results all guinea-pigs which died within twenty-one days of inoculation, we have deducted four guinea-pigs from the total number inoculated, these died as follows:-

(a) One on the 1st day after inoculation. (b) One on the 2nd day after inoculation.

(c) One on the 3rd day after inoculation.
(d) One on the 5th day after inoculation.
Three out of the four belong to groups in which two or more eventually became affected with tuberculosis due to inoculation of milk, thus:

(a) belonged to a group in which 2 out of 6 died

of tuberculosis.

(b) belonged to a group in which 2 out of 6 died of tuberculosis.

(d) belonged to a group in which 4 out of 6 died of tuberculosis.

It is reasonable to suppose that had they lived one or more of these guinea-pigs might have come under the heading of those that died of tuberculosis.

It has been found necessary to deduct a whole group, namely K It was noticed at the time of inoculation that K bore the name of the same dairy It was noticed at the time of as C, and later, post-mortem examinations and the construction of the tables of results disclosed the fact that two guinea-pigs, one from C and one from K, showed similar internal lesions. This led to an inquiry being made as regards the dairy, when it was found the same milkman supplied the two col-

leges.
Therefore out of the 100 guinea-pigs originally inoculated the following have been deducted:—

(a) Four that died within twenty-one days of inoculation.

(b) Six that belonged to Group K, which subsequently was found to be the same as C.

Results.-1. Of the 90 guinea-pigs inoculated, 23 died of tuberculosis, giving a percentage of 25:55. Of these 23 guinea-pigs 13 were inoculated with the creamy layer and 10 with the sediment.

2. Of the 16 dairies examined, the milk of 9 caused tuberculosis, i.e., the milk supply of more than half of them was tainted and capable of spreading tuberculosis.

These results may be given in tabular form.

Dairy.	Number of guinea-pigs infected with tubercle, as the result of inoculation with:		Evidence of Tubercle
	Creamy Layer.	Fediment.	the milk.
A	None	None	_
В	1 out of 3	1 out of 3	+

N	2 out of 3	2 out of 3	+
0	None	None	_
P	3 out of 3	None	+
Q	1 out of 3	None	+

It is thus evident that more than half of the 16 dairies examined, now supplying ten of the colleges, send out milk containing tubercle bacilli in sufficient quantities to cause tuberculosis in guinea pigs when these animals have been subjected to inoculation: it is therefore not unreasonable to regard these dairies as a source of grave danger. Again, these dairies supply not only colleges but the town as well, here the danger is much more marked as regards:

(a) Hand-fed infants,

(b) Young children, (c) Delicate people,

(d) All people suffering from acute diseases.

In these cases a milk diet is often considered neces sary, in some it is the sole diet. Some of these people cannot drink boiled milk, and therefore it is most important that they should not use milk containing tubercle bacilli. Whilst some authorities consider tuberculosis to arise solely from inhaled tubercle bacilli, it is probable that a very much larger number of human beings, and certainly of infants, contract that disease by drinking milk containing living tubercle bacilli.

Now it may be argued that almost half the dairies of Cambridge supply milk free from tubercle bacilli. Such argument would be extremely unsafe, for

(a) before we can speak favourably of a dairy we

should have to examine every animal separately, and (b) a dairy which three successive days sends out milk free from tubercle bacilli, a few days later may issue milk containing these bacilli.

The fact that more than half the dairies examined sell milk containing living tubercle bacilli shows how serious the matter is at the present time. Therefore, if we are asked how to avoid all danger of infection we answer,

(a) under existing conditions nothing but boiled or carefully sterilised milk should be consumed, and

(b) cream, unless obtained after boiling or scalding, should not be given to infants or delicate persons.

Ideal conditions demand that we should not rest content with anything short of the certainty that no milk is offered for sale except that obtained from cows known to be free from tuberculosis. We must, in fact, aim at introducing the system which Professor Bang has so successfully carried out in Denmark; at any rate it is our duty to protect those who cannot protect themselves.

THE LESSONS IN GYNÆCOLOGY OF A YEAR. (a)

BY H. MACNAUGHTON-JONES, M.D., M.A.O., M.Ch, F.R.C.S.I. and E.,

President of the British Gynæcological fociety.

GENTLEMEN,-In bringing to your notice some lessons in gynæcology learned during the year that has passed, I am induced before doing so to say a few words on the raison d'etre of a gynæcological society in this, the last year but one of the nineteenth century. At the recent Annual Dinner of this Society, the venerable and distinguished President of the General Medical Council, in proposing the toast of the British Gynæcological Society, made the pertinent inquiry, "What are the attributes which call, in its particular interest, for such a toast?" In other words, what has this Society done, and what is it doing. to entitle it to the esteem of the profession at large, and the respect of those who at the present time are working in the van of that department of medical science with which it has especially to say. I think it can be affirmed with absolute truth, that in no field of surgery have advances been more rapid and striking than in that of The workers of this century have handed gynæcology. on to those of the next, from out of the crude and chaotic elements in which they worked for many years, a system of treatment founded upon a solid basis of well ascertained anatomical, physiological, and pathological facts. Not only have we given to us a fairly complete codification of the different diseased conditions which attack the various structures entering into the component parts of the pelvic organs of women, enabling us to apply well-defined rules of surgical treatment, palliative or radical but these surgical procedures themselves have been most critically differentiated, so as to adapt them with the greatest safety to the woman, and the most skilful removal or conservation of the affected parts. A modern gynæcological operation, from its inception to its close, proceeds on well pre-determined lines in the execution of all its details, into which no haphazard methods, or any leanings on chance, are permitted to play a part. It would be superfluous to show the truth of this statement by referring to the many surgical procedures resorted to from the external organs of generation to the uterine aduexa, with which you are familiar. And it is well that a Society such as ours, professing to take its place in the forefront of progressive gynæcology, should realise clearly its position. It is with a scientific society as with any slowly evolving art: the developing stages consequent upon new acquisition of knowledge and technique leave behind them, imperceptibly it may be at the time, evidences of the disregarded practices and appliances which have gradually led up to its more complete, though possibly not perfect, development. It follows that at any particular time, when such evolutionary process is at work, we must have transitional phases between such obsolete views or practices, and the more perfect applications of the art which has grown out of them. Behind us is a well-defined line of demarcation separating now totally disused and antiquated modes of practice; before us lies a period of future possibilities, at which we aim through our instinctive dissatisfaction with even the most complete of our present procedures and results. A Society lives in this passing phase of dissatisfaction and distrust of itself, and its sole object is by record, observation and experiment, to advance still more to faultless and finished procedures. A Society does not exist to disinter dead hypotheses and practices, and of all the aggravating and useless expenditures of time, that of flogging the dead carcase of some jaded argument for the purpose of self-glorification is the worst. In gynæ-cology, for example, it is a fact established by many thousands of experiments that removal of every form of uterine tumour can be safely conducted by hysterectomy; that, with or without the uterus, the most extensively diseased adnexa can be removed by celictomy; that ovarian tumours, with every conceivable complication, can be dealt with successfully by ovario-

(a) Presidential Address delivered before the British Gynecological Society, January 12th, 1899.

tomy; that myomata of a certain kind can be most successfully ablated by the vaginal route; that certain adnexal conditions can be best dealt with in the same manner, and that conservative operations on these organs can be most successfully carried out by coloromy, anterior or posterior; that cancer of the uterus, save in very rare conditions, such as malignant disease complicated by a large myoma, is best attacked by vaginal hysterectomy; that drainage is not necessary, save under conditions which are fairly defined and settled, and that once having decided upon drainage, the mode of carrying it into effect, whether after laparotomy or vaginal hysterectomy, has been absolutely determined, and is a matter of every day routine.

To exhibit specimens merely to prove any of these points is an unjustifiable expenditure of valuable time. Also, it may with truth be said, that every argument that can conceivably be advanced in regard to certain details before, during, and after operative procedures, has been debated and written of to the death. I might take, for example, the preparation of the patient, so far as diet, the preparation of the bowel, the disinfection of the parts, and narcosis are concerned; the advantages of the Trendelenburg position and the employment, in emergency from collapse, of artificial serum; the method of closing the abdominal wound, and the abdominal toilette generally; the after treatment of a patient, and all the various complications which are incidental to all serious cases of abdominal or vaginal coliotomy. It is rather humiliating for a man to find that he has been absorbing time in discussing and ventilating his views upon subjects which he can—if he will only take the trouble—learn have been all exhaustively considered

some few years before.

But turning to these very points that I have taken for illustration, let me indicate some perfectly justifiable matters for discussion, which the exhibition of otherwise uninstructive specimens may warrant. We may broadly divide under three heads the exceptional circumstances or conditions connected with a case, which attach to it sufficient interest to make it worthy of discussion:—(1) Clinical facts, signs and symptoms, leading to difficulty and errors of diagnosis; (2) unique, serious, and unexpected complications arising during operation, which have to be dealt with by improvised methods calling for original suggestion and application on the part of the operator: (3) pathological conditions, the interest of which depends upon their rarity, or the bearing they may have upon treatment and the demand for, or the nature and extent of, operative procedures. In uterine fibroids there are still such debatable questions as the mode of there are still such debatable questions as the mode or securing hæmostasis in certain exceptionally difficult cases of hysterectomy, complicated by the presence of broad ligament tumours and inflammatory affections, or with growths of the adnexa; the man-agement of pregnancy complicated with fibroid; extra - uterine feetation associated with myound and adnexal disease and tumours; conservative treatment of the uterus by myotomy or enucleation of fibromatous tumours, as advocated before the Society recently by Dr. William Alexander. With regard to diseased adnexa, there are many interesting points bearing upon symptomatology on which much light may be thrown by more careful examination of the tissues removed, for it is a certain fact that pain, difficulty of locomotion, and various disturbances of the nervous system, are caused in some women by pathological changes in the ovary in no way proportionate to these symptoms, and for which no relief can be found save by removal of the diseased organs. Evidence is required drawn from the after history of cases of conservative surgery of the ovaries and tubes as to the results of efforts to save cystic and cirrhosed ovaries and tubes that have suppurated, or have been distended with serum or blood. Adnexal tumours which have a bearing on the question of the vaginal or abdominal routes of operation, through the adhesions which have formed, the size and character of the tumours, their association with fibromata or malignant disease of the uterus, have also a special interest. There is the question, both pathological and operative, of ovarian and broad ligament hæmatoma and blood cysts, with the bearing which these have no

the occurrence, as well as the histological and pathological sequences, of ruptured tubo-ovarian and tubal gestation.

Ovariotomy for ovarian cystoma must have occasionally certain complications which so involve the operation of ovariotomy that the narration of the case, independent of ary specimen for exhibition, cannot fail to be of importance. I refer to various types of blood cysts, suppurating and malignant cystoma, and such difficult complications as extensive peritoneal, omental and bowel adhesions, an extreme instance of which, occurring recently in my own practice, I shall presently refer to. And here I may advert to what appears to me to be a most important want in the proceedings of our Society, namely, the backwardness of our Fellows in bringing forward cases which have presented special features of clinical interest. There appears to be an idea that unless the proof of a surgical triumph can be obtained in the shape of a pathological specimen, such cases should be allowed to pass unrecorded. May I be permitted to say that there is a certain acknowledgment of defeat associated even with the greatest triumph in the removal of important organs. After all is told, it is but a demonstration that disease has baffled the physician and that nought save radical removal and mutilation have saved the patient. It would be easy to instance a number of affections of all parts of the sexual organs of supreme interest to the gynecologist, and more especially to the practitioner who may not look upon himself in the light of a special operator, which should find a place in our debates and Transactions, and which would give rise to most instructive discussion. Proofs of truly conservative gynecology would here find their appropriate place, and general therapeutics, including the administration of remedies, would at least be thought worthy of mention at the meetings of our Society. At present we seek in vain in our Transactions for evidence that any form of general treatment and medication, not to speak of any special drug, is of use in resisting the inroads of pelvic disease in women. Not long since I heard an able and distinguished gynæcologist, for whom I have the greatest respect, and whose operative skill is beyond question, declare jocularity, that he "knew nothing of physic." Surely prophylaxis, and treatment other than purely operative, have their appropriate place in anticipating and resisting the inroads of disease. Were it possible to show in the Gynecological Society, by some radio-graphic method, organs which had been threatened with, or passed through some critical and serious morbid change (during the stages of which the life of the patient had been in grave danger) now restored, physiologically and histologically to a condition of health, we must acknowledge that at least such an exhibition of living pictures would be more satisfactory to our patients than any number of dead specimens - though, of course, pathologically and financially, we should be the losers! Those of our Fellows largely engaged in general practice, as many of them are, could by such records considerably advance the interest and value of our debates.

In this direction the value of the ovarian secretion as a therapeutic agent is worthy of the most careful consideration. Indeed, the correlation between unstable protagon compounds, as lecithin, and the phosphatic compounds in the tissues, with the influence of both on nutrition and metabolism generally, has not yet been sufficiently studied. However this may be, the experiments of Curatulo and Turalli prove that distinct effects on oxidi-sation are caused by the removal of the ovaries and more curious still are the experiments of Krauer, which prove that even transplantation of the ovaries to distant parts does not affect the development of the Graafian follicles, nor does it change the normal structure, while Chrobak, with the ovarian extract of the cow, produced most important effects on symptoms due to the induced climacby the analogy existing between the thyroid secretion and that of the ovary, by the administration of thryoid tablets affected in a striking manner patients suffering from a variety of symptoms, mental and other, assumed to be due to deficient ovarian secretion. To Dr. C H. which are given by ignorant minds peculiar and possibly Routh is due the credit of having been the first in the strained significance, are there not points of vital moment

United Kingdom, and in this Society, to draw special attention to this physiological function.

I might instance questions of such common occurrence as the treatment of pruritus and eczema vulvæ, the management of granular vaginitis, the results of curettage in cases of hæmorrhagic endometritis, fungous endometritis, chronic suppurative endometritis, associated with suppurative conditions of the adnexa, and the all-important bearing of gonorrhead infection on inflammatory conditions of the uterus and adnexa. I include those facts of etiological and bacteriological moment which bear upon the life history of the gonococcus, its struggle for existence in the generative organs, the question of latency, survival, and reproduction, as well as the effect which the failure of detection of the organism may have upon our diagnosis and of the organism may have upon our diagnosis and

In this connection I may say that I view a negative result following the examination for the gonococcus as in no way disproving the specific nature of a discharge, its presence being dependent upon the date of infection, its duration, or fresh exacerbations and recurrent infection of the genital canal. But I believe that in the great majority of cases in which there is suppurative endometritis with double pyosalpinx, recent or latent genorrhosal

infection is the cause of the mischief.

The last example I referred to was drainage, and here again the relative advantage—under certain exceptional conditions—of different methods may be demonstrated, while, on the other hand, instances of harm following upon its adoption, and the best means of dealing with such ill consequences, might be shown. Mr. Jessett's ingenious method of dealing with a large rent in the bladder, which he brought this year before the Society,

is a case in point.

And speaking of the bladder reminds me that there is a large field open to the gynæcologist, and especially to our younger Fellows, to perfect themselves in the exploration of the bladder by cystoscopy, by repeated experiences derived through frequent examination. Two rival methods are in the field. The one which is familiar to all is that of Howard Kelly. This has the disadvantage of requiring an ansethetic, which is but a slight one, and the dilatation of the urethra in order to explore the bladder, or to catheterise and sound the ureter and kidney. The other method is that by means ureter and kidney. of the cystoscope of Dr. Kolischer, of Vienna, practised also by Professor Winter, of Berlin, which I here show you. Recently, through the kindness of Dr. Kolischer, I had the opportunity of seeing him demonstrate various morbid conditions in the Krankenhaus in Vienna, in Professor Schauta's Klinik, affections of the vesical mucosa, and exploration and catheterisation of the This was done without an anæsthetic, and ureters. without dilatation of the urethra, and thus medication was applied to the bladder wall without any difficulty. It is not necessary to say of what vital moment it is in diagnosis to determine the condition of a ureter, to catheterise a kidney, to ascertain which ureter or kidney is involved, and to perform certain operative procedures on the wall of the bladder, all of which can be done by means of this convenient appliance of Dr. Kolischer's.

Before passing from this brief sketch of some of the paths along which our Society may advance in the direction of original observation, research and operative technique, there is a matter that I will very briefly allude to, for it is a topic of such supreme importance to the profession that nought save a mere reference would be warrantable on an occasion like the present. Nor will I here express any opinion or enter into a discussion of my reasons for suggesting that it is such a Society as this which ought to seriously consider the propriety of reviewing the present position, in its medical or medico-legal bearings, of the whole subject of accidental or intentional abortion. Without, as I have said, pronouncing any opinion, I will ask the Fellows of this Society if they consider that the expert scientific evidence constantly brought forward is satisfactory, and such as is calculated to fulfil, without favour or prejudice, the ends of justice. Leaving out of consideration incidental circumstances, to both clinical and pathological, which are most loosely and inaccurately adjudicated upon? If this be so, would it not be well that a committee, composed of expert pathologists and men with large clinical experience, should be nominated to report on the entire subject, such report being founded on a careful investigation of published cases bearing upon it? It would take into consideration all the pathological points at issue needful to arrive at a correct conclusion, and, finally, it would sift all the clinical facts which have to be reviewed in such cases, and apportion to each its proper value when weighed in relation to all the antecedent and accompanying facts. It might be possible to associate with this body in its deliberations a few medico-legal experts, and one of our experienced medical coroners. Such a committee would require to sit periodically for some months, and should then furnish its report through the Council to the Society, which might amend it before endorsement, and this authoritative expression of opinion should then be forwarded to the proper quarters. venture to throw out this suggestion.

Before answering the natural question, "What has the British Gynæcological Society done during the past year to promote and advance our art?" I will in a few sentences summarise its work. I find that the following operations have been illustrated by interesting specimens exhibited by the Fellows: abdominal pan-hysterectomy, nine; vaginal pan-hysterectomy, ten; hysterectomy by cellotomy, seven; oöphorectomy, colpotomy, and ovariotomy for cystoma, seventeen; extra-uterine fotations, three; myomectomy, one. Special discussions have taken place on the treatment of dysmenorrhea, on hæmorrhagic endometritis, the question of the enucleation of uterine fibroids, on risks to the ureters during hysterectomy, and on the after treatment of cases of

abdominal section.

Addresses have been delivered on the operative treatmen of extra-uterine gestation, "the position of gynescology to-day," and combined abdominal and vaginal ovariotomy. If we now reply to the query I have asked, I think we may thus briefly summarise and condense the more important results of our work. Attention has been drawn to the necessity for a clearer differentiation in the etiology and treatment of hæmorrhagic endometritis, and inquiry into the etiological significance of syphilis in this disease; instructive suggestions have been made on the diagnosis and symptomatology of extra-uterine feetation; there has been an exhibition of a unique col-lection of microscopical specimens illustrative of the more rare pathological conditions of the uterus and adnexa: specimens have also been shown demonstrating the more frequent occurrence of sarcoma of the ovary. We have discussed the consideration of the comparative value of enucleation of uterine fibroids as a conservative operation, and as an alternative to hysterectomy and pan-hysterectomy; the importance of operation on uterine fibroma complicating pregnancy; the value of immediate opening of the abdomen when constriction or injury of the ureter is suspected after hysterectomy, and the comparative rarity of injury to the ureter when considered with the number of operations performed (only ten cases in several thousand of operations having occurred in the practice of such men as Martin and Landau of Berlin, Doyen of Paris, and Kufferath of Brussels), have been noticed. The question of the relative importance of Dudley's operation has been raised in cases in which it is specially indicated for dysmenorrhosa. Some debatable points in the after treatment of patients on whom abdominal section has been performed, and the consideration of the combined abdominal and vaginal operation in cases in which there are inflammatory states of the adnexa present, as well as a better understanding of the grounds on which the vaginal route is selected, have been before us.

I should not forget to mention an interesting demonstration which was given before the Society by Dr. Newman, of the different organisms which are found in the female genital organs. The address of Professor Martin, to which I have incidentally referred, and which has now appeared in full in the Journal of the Society, was latened to with deep interest by a large number of Fellows at a meeting at which such distinguished

gynæcologists as Professor Sänger, Dr. Theodore Landau, Dr. Howard Kelly, Professors Lapthorn, Smith Gardiner, Jacobs and others, were present. Finally, you have had published 645 pages composed of Transactions of the Society, original communications, records of clinical cases, reviews, and summaries of contemporaneous gynæcological work and research, in the Journal of the Society,

I think we may summarise, as a few of the more solid acquisitions in gynæcology of the past year, the following:—There has been a clearer differentiation of the cases in which vaginal fixation, ventro-fixation, or shortening and fixation of the round ligaments (Alexander's operation) should be performed. The last, it must be acknowledged, is every day gaining additional

ground on the Continent, both in France and Germany. The most important contribution to this question made during the year 1898 has been that by Dr. Doléris, of Paris, who has published the analysis of ninety cases of treatment of retroversion of the uterus by shortening of the round ligaments by the inguinal method. In four instances laparotomy was also performed for affections of the adnera, and the round ligaments were fixed in the abdominal wound. In the ninety cases there were two deaths, but these ninety only made portion of a series of four hundred operations, and one of the two was attributed to iodoform intoxication; the other occurred in a neuropathic hysterical woman in whom the autopsy showed that strangulation of the colon in the neighbourhood of the foramen of Winslow existed, there being no perito-In twelve cases there were temporary vesical troubles; iodoform erythema occurred in a few, phleg-masia dolens in one. The particulars of seven cases he records, in which the results were not satisfactory, but these seven had associated with the failure, pregnancies, and the shortening of one ligament alone, a mode of operating which he had resorted to thirteen times in cases of moderate retroversion. In only two cases was there complete failure. Such testimony as this to our distinguished Fellow's operation is one that he may well

be proud of.

There has been a more frequent resort to subcutaneous injections of artificial serum in cases of collapse during operation, or continued tendency to it after. The value of this treatment in cases of collapse in tubal pregnancy should be remembered. Further researches tend to prove that deciduoma malignum is a maternal endothelium, developing either during pregnancy or immediately after labour; that it is characterised by metastasis. The substitution (after curettage) of amputation of the diseased portion of the cervix (after Martin's method), for repeated and doubtful cauterisation is a substantial gain, so is the determination of the best method of closure of the abdomen by the triple suture, and the importance of the isolated fascial suture with careful adaptation of the cut edges of the fascia, so as to secure primary union in the prevention of hernia.

(To be continued.)

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.
MEETING HELD FRIDAY, JANUARY 13TH, 1899.

The President, Mr. Langton, in the Chair.

CLINICAL EVENING.

LOCALISED MYOSITIS OSSIFICANS FROM INJURY.

Mr. J. Hutchinson, jun., showed a woman, æt. 35, who dislocated her elbow in 1890. Six weeks later there was bony thickening in front of the elbow beneath the brachial artery, in the brachialis anticus muscle, checking flexion and limiting pronation. A skiagram showed that the humerus was free and that the swelling was not due to displacement of the coronoid process.

Mr. Eve showed a large irregular bony plate removed from the vastus muscle following a kick by a horse in the thigh, attended by extensive hæmatoma. A skia-

gram showed osseous growth separated by an interval from the femur. On cutting down they found a cyst of true bone, showing that the growth was not an ossifying sarcoma He thought it was an example of ossification in fibrous tissue from organised blood clot.

ENLARGED SPLEEN WITH THRILL AND BRUIT.

Dr. Crawfurd showed a man with a typical filarial history extending over fifteen years, under observation for eighteen months. At times a persistent thrill could be felt round about the umbilicus, which was intensified by pressure, the maximum point being just inside the spleen border, with a continuous venous hum over the spleen extending into the epigastrium. He discussed the various possible explanations of these phenomena.

ANTERIOR DISPLACEMENT OF TUBERCULOUS CARPUS WITH FORMATION OF A FALSE JOINT.

Mr. H. Curtis showed a young woman with anterior displacement of the carpus consequent upon tuberculous disease, dating from 1895, the radius being most affected. The result was the formation of a false joint. Skiagrams and stereoscopic photographs were shown by Dr. Mackenzie Davidson of this case.

PEMPHIGUS OF THE MOUTH, PHARYNX, LARYNX, AND SKIN.

Dr. J. S. RICHARDS showed a man, æt. 62, with a bullous eruption of the mouth, pharynx, larynx, and skin. A remarkable feature was that it had originated in the larynx, and had remained limited to that region for six months before attacking the skin. It began with a "roughness" in the throat, with cough and dysphagia, and he expectorated mucus tinged with blood. The mucus membrane presented numerous red patches which readily bled on being touched. After improving, a recrudescence took place in September, and bullæ appeared the arms, &c.

Sir Felix Semon recalled a case which he had seen many years ago which illustrated the difficulty of diagnosis in these cases when the eruption did not extend to the skin. As the patient had a specific history it was thought to be due to syphilitic direase, but anti-syphilitic treatment produced no effect. The conjunctive then became involved, with ultimate loss of sight of both

yes.

PROGRESSIVE MUSCULAR ATROPHY AFTER MEASLES.

Dr. Batten showed a case of progressive atrophy of the peroneal type after measles in a boy, set. 7. Three months after recovery from measles, which was followed by bronchitis and pneumonia, his mother noticed that he dragged his left foot in walking, and a few months later the right became similarly affected. The weakness had been progressive. Six months ago he began to lose power in the hands. No hereditary history. There was marked wasting of the muscles of both legs below the knee. He was unable to extend or dorsi-flex the foot, which tended to assume the position of equino-varus in walking, he raised the legs high to prevent the toes dragging on the ground. The knee-jerks were present and equal. Recto-vesical functions, normal. There was marked wasting of the thenar, hypothenar, and interossei muscles. Sensation normal, no fibrillary tremor. Electrical reactions under chloroform showed complete absence of response to Faradism in all the affected muscles with diminished reaction to galvanism. He referred to other recorded cases of the kind in which, when examined, changes had been found in the peripheral nerves and in the postero-median columns of the

Dr. Ornerod mention other cases of the kind occurring after measles, observing that as the disease was a rare one it was unlikely that the sequence was a mere coincidence.

TWO CASES OF COMPLETE HYPOSPADIAS, WITH CLEFT SCROTUM.

Mr. Kellock showed two children with complete hypospadias and cleft scrotum. The family comprised seven other children, most of them males, two being daughters, all normal. The elder of the two patients was six and a half years old. Labour attended by midwife, who remarked that genitals were much smollen.

Was thought to be a girl, and christened as such. Six months later, however, a testicle was noticed in the right "labum." After miscarriage she had another child four years later, who also presented something abnormal about the genitals. This child was christened as a girl, and was being brought up as such. There was a fairly well-marked penis. The under surface was marked by groove lined by mucous membrane. The scrotum in both cases was divided. The perineum in both was well formed and strong. Per rectum nothing like a uterus could be detected. He remarked that the diagnosis of sex in the younger child would have been difficult had they not the older child as a guide. The pseudo-labia were evidently composed of dartos, as evidenced by their contractility to cold, &c.

The President, Mr. Godlee, Mr. Robinson, and Mr. Morgan, mentioned other cases of the kind, Mr. Robinson's cases being females.

A CASE OF PROGRESSIVE MUSCULAR ATROPHY OF UNUSUAL DISTRIBUTION.

Dr. Perkins showed a man, æt. 48, who had malaria sixteen years ago in America. Seven years ago he had a bad fall, and four years ago he noticed a sensation of coldness with alternations of heat around the loin, followed by gradually increased weakness in the legs. Occasional incontinence of nrine. No history of lead or syphilis. The case was unusual, in that atrophy affected the trunk muscles more than the limbs. He also showed a boy, æt. 16, in whom the disease was either congenital or so early that onset was not marked. He presented general muscular atrophy. No change in electrical reactions, and knee-jerks active.

CASES OF SHORTENING AND EVERSION OF THE THIGH.

Mr. Godler said that in showing these cases his object was not to suggest that there was not such a disease as coxa vara, but only to show that the conditions described as associated therewith might be dependent upon entirely different conditions. He confessed that he did not know what was meant by coxa vara. Case 1. -Boy, æt. 6, symptoms began a few months ago, family history possibly suggestive of tuberculosis. Never any pain or trouble, but there was one inch shortening of femur with rotation of the foot outwards. Skiagrams showed that the shortening was in the neck of the bone. Movements at hip very free. Case 2.—Boy, æt. 18, with one inch shortening and eversion, but hip was almost completely ankylosed. Tuberculous family history. Began after a blow, but never any pain. Case 3. (not shown)--Man, æt. 23, conditions as above. Skiagram showed no mischief in the head of the bone, but neck was almost at right angle with shaft.

Mr. RAYMOND JOHNSON objected to coxa vara being described as a disease instead of as a deformity.

Mr. H. BERTRAM ROBINSON exhibited a case of

in a man, æt. 65, under his care at St. Thomas's Hospital. The tumour was first noticed some six months ago, but he had not sought advice owing to the absence of pain. The tumour in the right parotid region extends from the zygoma above to below the lower normal limit of the gland, pressing backwards on the external auditory meatus, and extending forwards on the masseter, as a nodular projection, with a well defined anterior margin situated in the socia parotidis. The tumour extends deeply behind the jaw, but does not interfere with the movement of the latter; there is slight bulging into the pharynx on the right side, and the growth possibly reaches into the zygomatic fossa, and has involved the upper jaw, for by transillumination there is only a very faint crescent of light on the right side below the eye. The glands in the neck are extensively involved as far as the supra-clavicular region. No secondary growths.

Mr. BARKER was not convinced that it was a case of carcinoma at all, pointing out that the enlargement might be due to senile tuberculosis. The nodular character of the growth was against its being carcinomatous.

A CASE OF PSEUDO-HYPERTROPHIC PARALYSIS.

Dr. Voelcker showed a boy, æt. 5, who was at first thought to be suffering from pseudo-hypertrophic para-

lysis, but subsequent observation in hospital had led him to doubt the correctness of the diagnosis. When eleven months old he had scarlet fever, and at two years bronchitis and convulsions. He never walked. On rising from the ground he did so in the pseudo-hypertrophic way. The only enlarged muscle was the triceps. The back was very arched, and there was a great tendency to fall backwards. The knee-jerks were present, and the ankle-jerk brisk. He thought it might be a case of cerebral sclerosis.

ELEPHANTIASIS OF ONE LEG.

Sir DYCE DUCKWORTH showed a girl, æt. 20, a native of Yorkshire, in whom transient attacks of swelling of the left leg, commencing three years ago, had been followed by permanent enlargement. The limb up to the groin was enlarged, hard, and brawny, and did not pit on pressure. She had been under treatment for ten weeks. Massage, electricity, and a liberal dietary had effected marked improvement, but the circumference of the limb was still markedly in excess of the other. As to its causation, she had never before been out of Yorkshire, the blood was about normal, and no filaria had ever been discovered. There was no evidence of visceral disease, and no signs of lymphatic involvement or of enlarged glands.

EPITHELIOMA FOLLOWING LUPUS ERYTHEMATOSUS.

Dr. Pringle showed a woman, æt. 45, with "Multiple Epithelioma of the Scalp, which had followed upon Lupus Erythematosus."

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF MEDICINE.

MEETING HELD FRIDAY, DECEMBER 16TH, 1898.

The President, Dr. J. W. Moore, in the Chair.

CHYLURIA.

SIE GEORGE DUFFEY called attention to the great similarity between cases of chylous ascites and of chyluria, but he found that there was much difficulty in tracing their causes. In some cases of chylous ascites, rupture of the receptaculum chyli had been discovered, but, on the other hand, most careful post-mortem examination had sometimes failed to show any rupture of the lymphatics, or of the receptaculum chyli. He mentioned that Charcot and other French observers had described several cases in which there was chronic peritonitis, advancing this as a possible cause of chylous ascites.

Dr. Knort related the case of a male, set 53, a widower, who had had syphilis about five years ago, and gonorrhoea in the early part of this year. Coincident with an eruption of the syphilitic type, he got chyluria, and the specimens of his urine at present were very rich in fat globules. He could find no trace of the filarise in the blood. The patient had complained of pain in the lumbar region, and a certain amount of uneasiness, but not actual pain, during micturition. Up to the present, there was no sign of clotting of the chylous urine.

Dr. Parsons mentioned a case of ascites in which Dr. Purser, who made the post-mortem examination found the fluid to be perfectly opaque and resembling milk. Dr. Purser recognised the nature of the fluid, but could not determine the cause. There was nothing to indicate a rupture of the receptaculum chyli. Dr. Purser then suggested that, owing to the increased pressure in the veins on account of the failure of the right side of the heart, the thoracic duct was unable to empty its contents into the veins, and consequently some of the lymph or chyle became extravasated into the abdominal cavity, hence the turbidity of the ascitic fluid.

The President thought enough had been said in this discussion to establish the existence of a non-parasitic chyluria, as well as a parasitic form, though most of the cases described in books were, no doubt, due to the Filaris Bancrofti.

MERCURY IN BEART DISEASE.

Dr. Wallace Bratty read a paper on mercury in heart disease. He quoted extracts from Stokes' work on

"Diseases of the Heart and Aorta," in which the value of mercury in some forms of heart disease is emphasised. The cases in which mercury is of special value are those in which there is general venous engorgement, due to chronic mitral valve disease. He prefers to give mercury in small doses repeatedly, in order to produce its diuretic effect. The plan he has found generally most effectual is to give about half a grain of calomel with or without digitalis, and squill, according to the state of the pulse every four hours, for from ten to fourteen days, and to counteract any tendency to free purgation by, if necessary, combining the mercury with small doses of opium. He noted the remarkable diuresis which follows such a method of administration, and how again this mercurial course may be resorted to with success when recurrences of failing compensation occur. He has seen mercury given in the above way succeed when it failed when given in only occasional purgative doses.

Dr. Bewley remarked that it used to be taught that in cases of Bright's disease, the worst thing the physician could do was to administer mercury, and also that opium was undesirable in the same disease. The author had shown, however, that mercury was good in small doese in chronic heart disease due to Bright's disease, using it,

of course, with proper caution.

Dr. MAETLEY said that having been Sir William Broadbent's house physician he was imbued with a great love for calomel, his teaching being that a good purge of calomel would clear the kidneys, and put them into working order by lowering venous pressure.

Dr. Langford Symms related a case of a lady, who, some years ago, used to have periodic attacks of cardiac dyspness, anassarca, and other evidences of cardiac lesion. After trying other remedies, she was treated almost exclusively with calomel, and since then, now four years ago, she had never had a recurrence of the disorder.

The President doubted whether mercury, in the form of calomel, blue pill, &c., had any direct action on the liver at all. It acted on the duodenum and unloaded the liver by sweeping the bile through the duodenum—that is to say, it had only an indirect action on the liver. He mentioned the case of a little girl suffering from chronic mitral stenosis, with every symptom of backwash. She derived great benefit from leeching round the anus, and he intended, after hearing Dr. Beatty's paper, to try calomel in her case.

Dr. Beatty, in reply, said that when he commenced to practice he had the same dread of morphia and mercury in Bright's disease as Dr. Bewley. He remarked, however, that Dr. Roberts, in his work on diseases of the kidneys, speaking of drugs useful in relieving pain, mentioned morphia, but makes no allusion to any danger connected with its use in those diseases. With reference to the larger doses which he was told Sir W. Broadbent employed, he recalled one case in particular where calomel was given successfully in purgative doses when small doses had not succeeded. It seemed strange that when they got patients well once with mercury that they continued well for a considerable time, a point to which Dr. Stokes had drawn attention in his work on heart disease.

A CASE OF RECOVERY FROM INNOMINATE ANEURYSM.

Dr. Craic read notes of a case of innominate aneutysm in which recovery had taken place after prolonged treatment by rest, a limited dietary, and large doses of iodide of potassium. The patient, et. 65, had suffered from "bilious attacks" all his life, but there was no history of syphilis. The immediate cause of the aneutysm was attributed to straining efforts in endeavouring to secure an evacuation of the bowels on April 11th, 1897. Ten days later there were present unequivocal signs and symptoms of the aneutysm, which were attested by Sir William Stokes, Sir C. J. Nixon, and Mr. Wheeler. The patient was kept in bed in the recumbent position for three months, during which period the diet was limited chiefly to milk, gruel, and fruit, ice was regularly applied to the tumour, a daily evacuation from the bowels was secured, and iodide of potassium (in doses amounting to a drachm daily) was administered, with occasional intermissions. The tumour became smaller, the pain and throbbing lessened, but the heart's action was variable, irregular, and intermittent. The second

Digitized by Google

period of three months he spent at Monte Carlo, and here the treatment was persisted in, but, instead of remaining in bed, he spent his days in the garden of the hotel reclining on an American rocking-chair, to and from which he was carried night and morning. Here his symptoms entirely disappeared. At the commencement of the present year he went to the Italian Riviera, where he began to walk about, and subsequently he migrated to Marienbad, where he indulged in plenty of walking exercise and in a more liberal diet. He returned to Dublin during the autumn, and when he was carefully examined on November 28th eighteen months after the onset-there was no trace of the aneurysm to be found, except a slight prominence and diminished resonance where the tumour had existed He still continued to take iodide of potassium, but in lesser doses and with longer intervals of abstention.

Dr. THOMPSON, referring to the use of chloride of calcium in the treatment of aneuryam, mentioned the case of a patient who was admitted into Jervis Street Hospital some years ago suffering from aneurysm of the arch of the aorta. the was put on large doses of chloride of calcium (20 grs. three times a day), due care also being taken to secure absolute rest. After remaining in hospital for about six weeks she left, the aneurysm having then diminished considerably in size. She returned twelve months afterwards with the aneurysm back again to its original size, and was once more treated successful with chloride of calcium. She then left once more, and died on her return this year. On post-mortem examina-tion two sets of fibrin deposits were found in the aneurysm, the first evidently corresponding to the first time she was in hospital, and the second to her subsequent sojourn in hospital.

Dr. CRAIG, replying, said that with regard to Dr. Thompson's case he thought that the two layers of fibrin within the sac of the aneurysm were accounted for by the

fact that the patient got two periods of rest.
Dr. J. LUMBDEN exhibited two cases of favus. The Section then adjourned.

LIVERPOOL MEDICAL SOCIETY.

MEETING HELD THURSDAY, JANUARY 5, 1899.

Dr. Macrie Campbell, President, in the Chair.

OPERATIVE TREATMENT OF GASTRIC ULCER.

Mr. Robert Jones related two cases where he had operated for gastric ulcer, one of which recovered and the other lived for fourteen days. In the first case, a girl of 19, the perforation had existed for three hours, and was situated on the anterior aspect near the pylorus. Some partially digested milk had exuded. There was no peritonitis. The ulcer was inverted and stitched, and the wound closed without drainage. She made an uninterrupted recovery. From the appearance of the ulcer, absence of anemia, and previous history of tubercle, Mr. Jones suggested the possibility of the tuberculous nature of the ulcer. The second case, a woman of 21, was operated upon fourteen hours after perfora-tion. She was very collapsed. A large indurated perforation was found near the cardiac end of the lesser curvature on the anterior aspect. There was exudation of partially digested food. Adhesions had formed with liver and abdominal parietes. There was considerable exudation of lymph, which had to be forcibly scraped. The ulcer was obliterated by a purse string suture, fortified by Lembert's stitches, and completed by stitching omentum over area. She did fairly well for fourteen days, when she vomited pus. Incision was made, and a peri-splenic abscess containing foul-smelling pus was discovered. She was very collapsed, and died twelve hours later. Post-mortem showed perforation to have quite healed. There was no communication between the wound area and the peri-splenic and sub-diaphragmatic abscess cavities. The diaphragm was burrowed through, and the lung opened into. There was no ulcer on the posterior aspect of the stomach. Mr. Jones quite agreed with the recent suggestion of Turner that the lesser sac of peritoneum should be irrigated, and the

posterior aspect of stomach inspected in nearly all cases. Mr. Paul made some remarks.

Dr. Buchanan demonstrated a case of myxodema in a man, æt. 54, treated with "Colloid" matters, according to Dr. R. Hutchinson's formula. The disappearance of symptoms was shown to be remarkable, and after four months' treatment the restoration to health was complete. The case was illustrated by lantern slides.

Dr. ALEXANDER related a case of "gunshot wound of brain."

Dr. Briggs exhibited a fibroid (weight 13th lbs.) removed on November 26th, 1898 (from a single lady, æt. 33), through an abdominal incision by hysterectomy, of which enucleation was the first step, because of the large thin-walled veins in the capsu'e and the difficulty of getting at the cervix and main arteries with the tumour in situ. The tumour reached low down on the cervix, and encroached on the right broad ligament. The right ovary was cystic. As soon as the tumour was released from its capsule, the large veins emptied their contents into the general circulation. There was little shock. The capsule and uterus appeared too big and too loose to be left behind with safety. The growth and uterus were originally equal in size to the eight months' pregnant uterus. In smaller growths the capsule and uterus might be left behind with safety, but enucleation alone of large tumours has not yet been shown to be equally safe.

Dr. A. E. ROBERTS read a paper on the

VACCINATION ACT, 1898, AND THE LOCAL GOVERNMENT BOARD ORDER OF OCTOBER 18TH.

He deplored the attitude of hostility which large sections of the community had assumed towards vaccina-There could be no doubt that these good people had given us a fall, and repudiated us and our work in this matter of vaccination. Not until some great calamity occurred would the insane agitation be stifled; meanwhile we are drifting into a position of grave danger. On the question of compulsion he was of opinion that, living under democratic institutions as we do, we must not be surprised if now and again the drawbacks of our methods of government should become manifest as well as its blessings. The duty of the profession is clear. It is, by every legitimate means, to instruct the people in this question. Probably we have been too lax in that respect, and allowed our friend the enemy to occupy the field. He particularly deplored the fact that a large number of objectors were animated by something resembling a high enthusiasm. They regarded their movement as a kind of holy war. We read of thousands in a neighbouring town crowding for exemption certificates singing "Christians, awake," and other appropriate hymns. It suggested, on the humorous side, a town's meeting gathered to denounce the multiplication table as an unholy invention of the devil; but it had its element of pathos in it. This potential, unconscious slaughter of their innocents by loving parents. He explained the provisions of the Act and order, and appealed for cordial relations between the public vaccinators and the private vaccinations under the somewhat trying circumstances of the public officer having to visit the homes.

The PRESIDENT, in opening the debate, remarked that probably no more retrograde step had ever been taken by Parliament, a step by which the majority had been handed over bound hand and foot to a fanatical minority. Calf lymph he found was responsible for a certain amount of insufficient vaccination. He had used calf lymph exclusively during the last lifteen years, and required to operate a second time in about 15 per cent. This gave rise to dissatisfaction among the friends. What, again, was to be done with cases in which only one or two marks took? He generally recommended revaccination at four or five years. The importance of cleanliness in skin and instruments was now well understood, and everything should be done to remove prejudice against the operation.

Mr. RUSHTON PARKER remarked that in spite of the disinterested advocacy and practice of vaccination by the medical profession the public seemed determined in England to take the risk of small-pox for some of their children. He, in common with the rest of our profession had felt at first greatly disappointed at the recent Vaccination Act. But whether the Government were wise in adopting it, or not, he deprecated blaming them, for it was evident that they were as individuals staunch adherents of vaccination, and only adopted this apparently lame and impotent device as being in their expectation more likely in the long run to maintain the practice of vaccination, than the order for its compulsion, which had unfortunately not been administered successfully, owing to laxity on the part of the officials deputed to enforce it, upon a democratic community who largely refused to be coerced in this matter. He desired to compliment Dr. Roberts on the matter and style of his paper.

Dr. Hugh Jones called attention to two statements in the report of the Royal Commission that vaccination was protective against small-pox, and that vaccination could not be replaced at present efficiently by other preventive measures. There was, however, another side, isolation, notification, disinfection, as subsidiary measures ought to receive their full credit, and the hope of the future for the extinction of infectious diseases depended

chiefly upon efficient sanitary measures.

Dr. Hope considered that the present grave condition in respect to vaccination was contributed to by the long period, extending over many years, which the Royal Commission took before publishing their conclusions. During those years the opponents of vaccination were extremely active, and, unfortunately, very successful. He pointed out that the Bill introduced by Mr. Chaplin differed very widely from the Act which was ultimately passed, an Act which was in absolute and direct antagonism to the carefully considered recommendations of the Royal Commission, whose exact words are: - "We are of opinion that the State ought to continue to promote the vaccination of the people." "We can see nothing to warrant the conclusion that in this country vaccination might safely be abandoned, and replaced by a system of isolation."

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

ORDINARY MEETING HELD AT OWENS COLLEGE, MANCHESTER, DECEMBER 16TH, 1898.

The President, Dr. J. W. MARTIN (Sheffield) in the Chair.

 Dr. Donald (Manchester) showed a "myoma of the uterus," about the size of an adult's head, removed by abdominal myomectomy. There was considerable difficulty in enucleating the tumour, the capsule measuring half an inch in thickness, and being composed of hyper-trophied uterine wall. There was very small hemor-

rhage from several vessels in the capsule.

Dr. Donald also showed an "uterus removed by vaginal hysterectomy," after perforation by sounds. The cervix was being dilated preparatory to curetting. There was no resistance at any part, and the sound passed easily six or seven inches. An examination of the abdomen showed that the point of the instrument was in the abdominal cavity. A No. 12 dilator was introduced with the same result. As it was evident the uterine wall was perforated, and as the contents of the uterus were undoubtedly septic, the anterior vaginal fornix was opened up, and the fundus uteri brought into view. Two large apertures which had evidently been made by the dilators were found in the fundus, and the uterine tissue was so friable that vulsellum forceps very easily caused tearing Vaginal hysterectomy was performed as the safest method of treatment. Probably the degeneration of the uterine wall was due partly to frequent chi dbearing, and partly to septic processes following miscarriage.

CASE OF PUERPERAL SEPTICÆMIA TREATED SUCCESSFULLY BY INJECTIONS OF ANTISTREPTOCOCCIC SERUM.

Dr. GRIMSDALE read notes of a case of the above. The woman, æt. 35, had an easy labour, followed by a rigor in forty-eight hours. Her medical man treated her energetically by washing out the uterus and curetting it, but the symptoms of high temperature, quick pulse, rapid wasting, and general serious illness persisted. On

the ninth day of the disease Dr. Grimsdale saw her, and admitted her to the Royal Infirmary. Streptococci having been found in the blood serum, injections of ten cubic centimetres were made into the flanks. After two injections the patient, from having a temperature 104° F., and pulse 120, became apparently convalescent with normal pulse and temperature. The injections were stopped. The temperature remained normal for 24 hours, but rose gradually, so that in three days it was 103 degs. F and pulse 120, while the temperature was normal. Streptococci were found to be present in the blood. After the recurrence of the fever injections of 10 cc. of the serum were given for fifteen days consecutively. The micro-organisms had then disappeared from the blood and the injections were discontinued. At this time the temperature was raised to 101 degs. F, but gradually fell, and the patient was discharged, cured. After admission to hespital no treatment was directed to the uterus, and beyond quinine no drug was used. Urticaria and severe pains in the limbs were complained of towards the end of the serum treatment, but this subsided in about a fortnight.

Dr. NESFIELD (Manchester) thought that the treatment of puerperal septicemia by anti-streptococcic serum, seemed scarcely a natural plan, inasmuch as it was using an alternative solution of the same poison as produced the disease, and that those cases which asted a long time usually ended in recovery under

very varied plans of treatment.
Dr. Abnold Lea (Manchester) considered that since at one period the streptococci disappeared entirely from the blood and returned again in a few days, a local source of infection must have been present, and that this was probably in the uterus itself, since there was no evidence of local pelvic trouble. He thought that if in similar cases the serum treatment failed, and the patient was losing ground, removal of the uterus through the vagina would be the best treatment.

Dr. Fothergill (Manchester), seeing that there was no physical sign or symptoms of any pelvic trouble, and that there was no foul discharge, considered this might be one of those cases of infection by the bacterium coli commune, through the wall of the intestine. Vaginal and uterine douching would be quite unnecessary in such a case, and when the streptococcus had once got into the blood, the use of the serum was the proper treatment.

Dr. Grimsdale, in reply, stated that the streptococci were present in the blood continuously; there was no disappearance and reappearance.

Dr. Bishop (Manchester) read a note on the vagino-abdominal incision versus morcellation, in some cases of pelvic surgery.

France.

Paris, January 15th, 1899.

THE DANGER OF THYROID MEDICATION.

AT the Académie de Médecine M. Franck read a paper in which, after enumerating the good effects obtained from the administration of the thyroid gland in affections due to suppression or insufficiency of the functions of the thyroid gland, insisted on the dangers which could result from the employment of this treatment where no trouble existed in the function of the gland, and notably in cases of simple obesity. It should not be forgotten that the thyroid juice is an extremely toxic product, producing somnolence, coma, &c., which caused the death of a certain number of patients from cardiac collapse. Consequently the speaker proposed that the Academy should pass a vote pronouncing thyroidian products as extremely dangerous, and forbidding the sale except on a doctor's prescription.

M. Lancereaux said that he agreed completely with

his colleague on the danger of the substance, and thought that the sale should be restricted. For his part he always suspended its use when the pulse beat over 100 times in the minute. M. Potain observed several patients in whom the administration of preparations of the thyroid gland provoked very serious symptoms. It was the more important not to leave these preparations at the disposition of the public as they can never judge of the counter indications of their employ, and when accidents occur it is frequently too late to arrest them M. Huchard considered the employment of thyroid preparations as extremely dangerous where the heart was affected, and said that he would vote the proposition of the first speaker.

GASTROTOMY.

M. Ligars presented a young girl, æt. 21, who in an act of folly swallowed a pile of pence. Three weeks after wards she expelled three penny pieces, and then told what she had done. She complained of great difficulty in swallowing and of pain in the epigastrium, while she vomited incessantly. By the radiographic examination an agglomeration of foreign bodies was observed at the cardiac extremity of the esophagus and another in the centre of the stomach. Gastrotomy was practised on December 12th, and six coins removed with great difficulty from the inferior extremity of the cesophagus. Recovery was rapid.

SENILE PRURITUS.

Professor Parisot, of Nancy, considering that autointoxication plays an essential role in the ætiology of generalised senile pruritus, has recourse to intestinal antisepsis in the treatment of this obstinate affection After purging the patient he puts him on milk diet, and prescribes daily doses of half a drachm of benzonaphthol. This treatment, of which the first favourable results are witnessed at the end of twenty-four hours, rapidly removes the violent and tenacious itching.

> ACUTE RHRUMATISM. Salicylate of soda, 3 j. Iodoform. 3 ij. Ext. of hyosciamus, 3 j. Vaseline, 3 iii.

Germanv.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 13th, 1899. At the Society for Internal Medicine Dr. Benda had a note on the

POINT OF ENTRANCE IN ULCERATIVE ENDOCARDITIS.

It was to be looked upon as a secondary disease, but the connecting point between it and the primary was only rarely demonstrated, and the transmission of the disease germ from any ulceration into the circulation could only occasionally be proved. He showed two cases in which this transmission could be followed. One was a case of ulcerative endocarditis with suppuration in the pelvis of the kidney, and a feetid abscess in the region of the kidney from a case of renal calculus. By Gram's process non-colourable bacteria belonging to the group of bacterium coli were found, which were the cause of the endocarditis. The second case was one of ulcerative endocarditis, set up by streptococci from a tonsillar abscess. Here numerous streptococcus thrombi wer found in the smallest veins and accumulation of cocci amound tham

THE TREATMENT OF OBESITY WITH THYROID GLAND PREPARATIONS

Such as the thyroidine pastilles of Bayer (Wien. Med. Wochensch.), in 0.3 doses. For six to ten days two pastilles a day were given, then a three days' pause; then for six to ten days two and a half were given, then another pause of three days, and then three were given daily from six to ten days.

Unpleasant symptoms were only due to faulty preparation, and not to the thyroidine, and the writer had never observed any. Even in the case of a woman who suffered from cardiac insufficiency, no ill effects on the heart appeared, but a distinct improvement in the function took place from the unburdening of the heart of its mass of fat. The diminution in weight from melting of the fat and excretion of water was never at the expense of the muscular tissue, for the patient became much stronger. This was in accordance with exact investigation into tissue changes.

Caution was necessary with the above doses, as, indeed, in all other methods of treatment of obesity. In the plethoric form of obesity the diet should be regulated along with the treatment, while in the ansemic form iron should be given. In old people, patients with valvular disease, arterio-sclerosis, albuminuria, and diabetes, thyroidine was contraindicated. The pastille treatment was not absolutely reliable, as one of the cases proved quite refractory.

THE PATHOLOGY OF MYXCEDEMA.

Dr. W. Muratow, in the Neurolog. Cbl. describes the carefully carried out examination of a fatal case of this disease. The patient was a girl of six, and the disease was congenital. The body showed the following changes :-

- 1. Toxic affections of the cortex (swelling of Nissl's corpuscles, and patchy dark blue staining of the basic substances).
- 2. Affection of the subcortical association tracks (delayed development starting from the cortical cells).
 - 3. Complete absence of the thyroid gland.

The psychical symptoms peculiar to the disease were explained by the serious anatomical lesion of the cortex According to Horsley, the functional activity of the thyroid began from the sixth to the eighth month of embryonic life. The higher nerve centres were in process of development at this period. The toxins here not only set up functional disturbance but arrested development. For this reason the psychical function suffered more in the case than in that of an adult. In the case of the latter, thyroid treatment removed the chronic toxemia, and with it the psychical symptoms. In infancy, in spite of the elimination of the toxin, the psychical activity only corresponded to that of an imperfectly developed brain.

At the Medical Society, Hr. Pick showel macromicroscopic preparations of

Syphilis of the Peritoneum and Amyleid of the FEMALE GENITALS.

The patient, a woman, set. 56, taken ill in December. 1896, with palpitation, pains in the head, &c. The medical attendant found ansemia, a syphilitic saddle-nose, and a large nodular liver that reached three to five finger-breadths beyond the ribs. The woman knew nothing of any infection, but the diagnosis was not in

Digitized by GOGIC

doubt. Eight years after marriage she had sore throat and the bones of the nose sank, and other symptoms were present. Potassic iodidum was not well borne, and inunction failed to do any good. Atrophy of the liver took place, and ascites came on, for which she was tapped twice. Then homocopathic treatment was carried out until the day before her death. The post-mortem examination showed cedema and ascites (18 litres) typical syphilitic liver and spleen, fatty degeneration of the kidneys, and above all, on the parietal peritoneumbetween the umbilicus and symphysis pubis, miliary, flattened nodules, the size of hemp seeds (some larger), of a yellow opaque character. All showed contagicentral depression like molluscum osum. Microscopically, they resembled tubercle, but this they were not. Gummatous peritonitis offered many analogies to gummatous periostitis. Literary observations on the subject were, however, rare. Amyloid degeneration of the genital organs was also very rare; in this case it affected the uterus, tubes, ovaries, the small arteries, capillaries, heart and lymphatics. Clinically it was noteworthy in so far as it gave a striking denial to the views of the anti-mercurialists, who would attribute cachexia and amyloid degeneration to the mercurial treatment itself, as, at the time these changes appeared, the patient had had no mercurial treatment at all. It showed that the pure virus alone had been the cause of all the amyloid changes.

Hr. Virchow, to whom the preparations had been previously shown, had sought through the specimens of the Pathological Institute for similar cases, and had found a preparation from the year 1856 of a woman who had died of Bright's disease with dropsy, who presented a condition analogous to Pick's case. There was circumscribed tuberculosis, not on the peritoneum but on the pleura, but no traces of the disease anywhere else. There was further widespread amyloid disease in the principal organs, the intestines, stomach, spleen, liver, heart, and uterus. The parallel of the case with that shown by Pick was a far-reaching one. speaker could not at the time make up his mind as to a diagnosis; in the catalogue he called the case "tuberculosis idiopathica?" He had now no doubt that it was a case of either miliary gumma formation or syphilitic tuberculosis.

Continental Aotes.

[FROM OUR OWN CORRESPONDENT.]

THE RIVIERA.-HYERES.

THE Fashoda and subsequent diplomatic discussions between France and Great Britain, the Dreyfus disputes and monarchical manifestoes at Paris, and the continued controversy about the health of Nice in the Standard, Herald and local journals have not added to the number of British visitors this winter to the Riviera. Since the advent of the New Year, however, the incoming trains have been better laden with passengers, and there is yet abundant time for a profitable season. The municipal authorities at Cannes and Nice are making extra arrangements for a more than usually brilliant carnival season and will doubtless be successful in attracting to this coast a large number of visitors for February and March.

Some of the quieter hibernal stations, like Hyères Grasse, and Antibes have a steady clientèle of winter guests, and have not so much cause of complaint as the gayer resorts. Hyères is always in favour with many people, who thoroughly appreciate its unquestionable advantages, and who enjoy its dry, warm, and mild, yet tonic climate, its luxuriant foliage and beautiful flora, its picturesque situation, and convenient excursions.

The comparative economy of residence either in the excellent hotels, or the pretty villas and comfortable apartments of Hyères, recommends it to many families who can find the comforts of English home-life, and the amusements of an English country life cheaper at Hyères than at any other equally desirable winter resort on the French Riviera. For invalids and delicate constitutions Hyères can be strongly recommended because of its exemption from too sudden changes of temperature.

BORDIGHERA.

The first winter station across the Italian border, Bordighera, is rising into favour. It is more economical than many of the French Riviera towns, and although near, less depressing than Mentone. You see fewer invalids here than at Mentone, and while life is less gay than at Monte Carlo or Nice, those who seek it can find abundant amusement; for in addition to its beautiful walks and interesting environs, its proximity to San Remo on the one side, and Monte Carlo on the other side, make Bordighera a convenient centre for those desiring the "distractions" of Riviera life.

Bordighera as a health resort is a modern creation. Ruffini's novel of "Don Antonio" earliest attracted English attention to the place by its eloquent descriptions of the charms of its surroundings. Since the patriot author's day other writers have likewise made the spot known; as Mr. Fitzroy Hamilton in his interesting work on the Italian Riviera, Mr. Clarence Bicknell by his standard books on the flora of the coast, and the genial Scotch novelist by selecting it as his winter home.

The old town is situated on a bold, green eminence. and around the railway station on the plain below to the westward, on the seashore, a modern village has gathered, containing the banks, post-office, libraries, some hotels, and shops. Half-way up the slope of the hill are most of the villas, the museum (free to all visitors) of Mr. Bicknell, the English church, and the newest In the principal of these new hotels, the Grand Hotel Angst, the Empress Frederick has engaged apartments for herself and suite. The hotel has fine grounds and groves of olive and orange trees interspersed with rose gardens and flower beds extending far up the hill behind the hotel. Into these grounds and gardens a private bridge leads from the Imperial apartments, so that the illustrious guest can promenade with strict seclusion. From the balconies on the front of her salons the prospect is one of great beauty, extending far out to sea, and taking in the picturesque coastline from San Remo to the Esterel range; on clear days Corsica is clearly visible, and the Maures Mountains beyond Hyères.

Bordighera has a pretty English church (become too small for its growing congregations), a large free library, and, what is very desirable for British residents abroad, four English physicians; one of them Dr. Guilio Hamilton, very favourably known in medical circles in London and Dublin.

The Operating Theatres.

ST. PETER'S HOSPITAL.

CASES OF INTERNAL URETHROTOMY .- MR. SWINFORD EDWARDS operated on two cases by internal urethrotomy. The first done was complicated with a perineal fistula; it was that of a man, æt. 55, who was admitted to the hospital with a discharging sinus in the perineum and a high temperature; he looked very ill and complained of great difficulty in passing water. On examination of the urethra a tight stricture was found in the sub-pubic region; there was also considerable contraction of the meatus. The patient was kept in bed, and placed on boracic acid mixture with a view to sterilising his water. After two or three days internal urethrotomy was performed in spite of his temperature being still above normal. A meatotomy was first done, the meatus being cut downwards with a blunt-pointed straight bistoury. Mr. Edwards then passed a filiform corkscrew pilot bougie to the end of which a Teevan-Maissonneuve's instrument was screwed and pushed on into the bladder; the knife having been placed in position was passed along the director and made to divide the stricture upwards in the roof of the urethra. The instrument having been withdrawn, a series of steel sounds were passed, ranging from twelve to seventeen English, and the operation was completed by washing out the bladder through a silver catheter with 1 in 6,000 sublimate solution. The patient having now been placed in the lithotomy position, the operator turned his attention to the perineal fistula, which was laid open on a director; two or three branching sinuses were discovered, which were similarly dealt with; when the finger was placed in the wound a steel sound in the urethra could easily be felt, though in this case it was not absolutely exposed. The sinuses were all thoroughly scraped, the overhanging edges of skin trimmed off, and the sinuses packed with gauze, the wounds being thus left to heal by granulation.

The second case was that of a young man, st. about 30, who had several strictures in his penile urethra with a tight one at the junction of the bulbo-membranous urethra. Internal urethrotomy was performed on this patient in the same manner as in the preceding one, the only hitch in the proceedings being that there was some little difficulty in getting the screw connection between the director of the urethrotome and the pilot bougie to pass through the very tight sub-pubic stricture, although this screw connection only equalled No. 9 French gauge.

Mr. Edwards drew attention to the small amount of bleeding which took place in both these cases, and what little there was in the first case was almost entirely due to the meatotomy. It was his experience that by this method of operating no serious hæmorrhage was to be feared; he considered that no matter whether a stricture situated in the deep urethra was divided on the roof or the floor, there was never any danger of serious hæmorrhage as long as the stricture was not cut beyond 22 French gauge. In order to get further dilatation, a series of conical steel sounds are passed, which probably further ruptures any stricture tissue which may have escaped the knife, that is to say, in a longitudinal direction, the rupture caused by the sound being limited to the longitudinal wound already made by the knife. When a larger cutting blade, such as one of 24 or 26 French gauge, is used, he had seen serious hæmorrhage follow. Indeed, he recol-

lected a case in the practice of a friend where death from hæmorrhage followed the employment of a 26 blade. He remarked also that in the first case he considered that the high temperature was no bar to an operation, but, on the contrary, rather called for it; as he had several times seen urinary fever due to stricture give way immediately after complete division of the stricture accompanied by antiseptic treatment of the bladder. It would be noticed, he said, that no attempt at a plastic ope. ration was made for the cure of the perineal fistula, for these cases generally made a rapid cure when treated by the method employed, the key-stone to the whole procedure being the restitution of the normal calibre of the urethral canal which was effected by the internal urethrotomy, and by the following dilatation. With regard to the second case he said that had he not been successful in following the pilot with the urethrotome, one of two methods would have been open to him: the first being to have left the pilot in situ for a matter of twenty-four hours, by which time the stricture would probably have dilated sufficiently to allow the passage of the urethrotome; the second would have been to have withdrawn the pilot and endeavoured to have effected some slight dilatation by the passage of one of Bang's conical whalebone bougies, a proceeding which he had employed successfully on several occasions; internal urethrotomy would then forthwith be completed in the usual manner.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 18, 1899.

THE LOCAL GOVERNMENT BOARD.

The resignation of the Permanent Secretary of the Local Government Board, Sir Hugh Owen, is an event of no little importance to the community in general, so far as the progress of local administration is concerned. This event affects the medical profession chiefly in the Poor-law and the public sanitary services, both of which strike deep down into the life and welfare of the nation. As an individualist and a man of great abilities and character, Sir Hugh Owen acquired an almost supreme influence in the Department which he has served for so many years. It is to be hoped, however, that the individual sway of public servants in Government offices will, ere long, give way to that of recognised principles enforced by an educated Parliament, and by strong and able ministers. That the present policy of the Poor-law is halting and erroneous is a doctrine firmly held by many thinking persons. The pauper poor, who are always with us, have been recognised as having a moral and legal claim to support from the more fortunately placed members of the community. Hence. any enlightened interpretation of the Poor-law would cede the relief thus granted as a right rather than as a dole to be extracted in fear and trembling and at the cost of heavy civil disqualifications. If that be true of pauperism in general, it is a thousand times more so as regards the aged and the sick poor, for whom help becomes simply a righteous demand and a bounden duty. Yet the evils of proper classification, of pauper nursing, of unskilled attendance upon lunatics and imbeciles, of understaffing of nurses, and of other gross defects of medical administration, are at this day flourishing rampant throughout the length and breadth of the United Kingdom. As to outdoor medical relief, it is only in a few towns reduced to anything like a proper system; while in most places it savours of the worst forms of parochial arrogance, delay, and degrading disqualification. Any system, indeed, stands self-condemned that entails upon a hard-working man of irreproachable character the loss of his parliamentary vote if he happen to be treated for, say, pneumothorax or enteric fever, in a Poor-law infirmary. The first duty of any strong and conscientious central board should be to classify paurers, and to simplify, amend, and codify the present chaotic rules of administration. An attempt, as everyone knows, has recently been made by Mr. Chaplin to introduce a rational treatment of metropolitan pauper children disabled in various physical directions. His action, however, affords an excellent instance of Local Government Board dilatoriness and want of judgment. His famous order placed the carrying out of a much-needed reform in the hands of an already everburdened body, the Metropolitan Asylums Board, with the result that some years later the matter appears to be more or less at a standstill. Indeed, dilatoriness is one of the chief indictments that can be brought against the policy of Sir Hugh Owen. Reports of responsible and highly-qualified Government inspectors have been neglected year after year, until the occurrence of some grave scandal has necessitated an official investigation. In some cases inquiry after inquiry has been held, schemes submitted, altered, reinvestigated, and in the long run carried out only after the lapse of years, or even shelved altogether. Then, when a dispute has arisen between some local authority and its medical officer, the latter has only

in the rarest instances received any atom of help

from the Local Government Board, no matter bow zealous and efficient his services, or how just and righteous his case. That attitude, indeed, may be said to sum up in a nutshell the main principal of Sir Hugh Owen, namely, that the loval authorities should be let alone as far as possible to attain salvation after their own light and after their own methods. It is to be hoped that henceforth a new spirit will come over this Department, which is in many respects one of the most important to the future of Great Britain. the Local Government Board has done magnificent work in the past no one can deny. At the same time we suggest that their machinery is now a little rusty and out of date, and that their methods are not quite up to modern and reasonable democratic standards. It seems likely that a first necessary step towards reform would be the entire separation of the Poor-law and the public sanitary services, with, possibly, the establishment of national scientific research laboratories. To attempt to bring all these diverse functions within the grasp of a single board is to court inefficiency, extravagance, and the hundred and one evils of an iron bound, non-progressive officialism.

STATE REGULATION OF MARRIAGE.-II.

In our previous remarks on this subject we discussed some of the disquatifications for marriage under the heads of: -1. Inebriety, Pauperism, and Criminality; 2. Insanity, Epilepsy, and Tuberculosis. We now pass on to consider. 3. Gonorrhæa and Syphilis in the Communicable Stages: Here we have to do with quite a different subject, and we may say at once that we believe that the help of legislation is urgently needed.' Not for the sake of men; it is well known that the great majority of men suffering from syphilis or gonorrhœa have contracted the disease before marriage; they knew the risks of illicit intercourse, and have paid the penalty of their folly. It is mainly for the sake of innocent wives and children that the law should step in. A woman can tell if she is marrying a lunatic, a drunkard, or a man in consumption, but she cannot tell whether the man she is about to marry is suffering from active syphilis or gonorrhea. And yet the results to her and to her children, if she has any, are of the most appalling and far-reaching character. What is the indictment against these diseases? We quote Dr. Burr, who has understated rather than overstated it:-"That gonorrhœa is accountable for most of women's pelvic woes; that it is the greatest cause of sterility in both sexes (Keherer); that it is the greatest single cause of blindn ss-185 to 235 per cent. of all the blind in early life being from this cause alone (Magnus, Fuchs and Lucius Howe); that it often kills, and that from this cause alone a license to marry may prove a deathwarrant to a confiding bride. That syphilis, of all diseases, is the greatest cause of abortion; that onethird of all syphilitic pregnancies abort or are stillborn; that one-third of those born alive die during

the first six months (Carpenter and Grassowitz); that the remainder are more or less enfeebled, deformed, or short-lived through lowered vital resistance; that locomotor ataxia and certain forms of insanity are almost synonymous with so-called tertiary syphilis." All medical men can testify that these things are true, and all those who have had experience of gynæcological out-patient practice at hospitals can form an estimate of the extent The subject, unfortunately, does of the evil. not lend itself to popular exposition; the revolting forms of suffering endured by many innocent women, and forming, within a few months of marriage, a heartbreaking awakening from their early love-dreams, cannot be openly spoken of, they can only be borne in silence by those whose health and ideals have been shattered at one blow. But the law provides a remedy-separation, divorce! remedy is it to a man whose eyesight has been destroyed by violence that his aggressor is separated from him? Prevention is what is wanted: and this might be secured by a law providing that an applicant for marriage should produce a certificate that he was not suffering from gonorrhea or syphilis in the communicable stages. Dr. Burr sketches out the working model of a Bill for this purpose. As it is a definite attempt in the right direction, its reproduction here needs no apology.

A Bill

for an Act to Revise the Law in Relation to Marriage. Section 1.—Be it enacted, by the . . . of the tate of . . . That it shall hereafter be unlawful to issue a license to marry to any applicant for such license who fails to present with his application a certificate, as hereinafter provided, setting forth that the applicant is not the subject of acute or latent gonorrhea, or syphilis in the communicable stages.

Section 2.—The certificate required shall be accepted from any reputable physician who is a member in good standing of the National, State, County, City, or other similar recognised organisation of the school of practice to which he or she belongs [that is, for British requirements, from any registered medical practitioner], and shall be in form and substance as follows, to wit:

State of . . County of . . .

I . . . M.D., a legally qualified physician and member in good standing of the . . . whereof . . . M.D. (address . . .) is Secretary, do hereby certify that I have examined . . . resident of . . . an intending applicant for license to marry, and that my examination, made with due skill and thoroughness, and during a sufficient period of time, fully satisfied my professional jadgment that said intending applicant is not the subject of any of the disqualifications for marriage specified in Section 1 of the Act to revise the law in relation to marriages, approved . . . 189... in force 189... I do, hereby, further certifive that this certificate is given with a full realisation of the sufferings entailed upon wives and offspring by marriage with the subjects of said disqualifications. Witness my hand this . . . day of . . . 189...

M.D. Address Section 3.—The physician's certificate shall be dealt with in the same manner, as to registry, endorsement and preservation, as is now prescribed for the certificate of marriage

Section 4.—All Acts or parts of Acts inconsistent, or in conflict, with this Act are hereby repealed, and this Act shall take effect and be in force from and after its passage.

Legislation on these lines would, apart from its direct results, be of incalculable benefit by drawing public attention to its objects. Something at least would become known concerning the prevalence of these maladies and the frequency of their distribution to innocent, unsuspecting wives and their helpless babes; and thus "the public would learn the truths concerning evils which the profession knows full well but upon which it is powerless to give public instruction, and against which, unaided by law, it is powerless to enforce protective measures.'

Rotes on Current Topics.

Popular Bacteriology.

It is, no doubt, desirable that the public should be afforded facilities for becoming acquainted with the general principles of bacteriology, as far as they apply to the dissemination, the cure, and the prevention of disease. Some caution is, however, necessarv in the choice of materials, and the lecturer would be well advised to avoid as far as possible undue optimism and hasty generalisations. inhabitants of Camberwell were recently treated to a lecture on the subject by Mr. Bousfield, the recently appointed bacteriologist to the parish. Curiously enough Mr. Bousfield repudiates any desire to pose as a specialist, though one would have supposed that a gentleman who holds a public appointment as a bacteriologist must of necessity be a specialist. The lecture in question, though embellished by lantern projections of the more common organisms of infectious diseases, was really almost entirely restricted to the subject of diphtheria, and in this connection the lecturer delivered himself of sundry statements which appear to us somewhat in advance of contemporaneous science. He is reported to have said that "vaccination sank into insignificance whencompared with the beneficent results of the antitoxintreatment of diphtheria," a statement which will not commend itself to our readers either by reason of its accuracy or of its opportuneness. It is absurd to pretend that the benefits that have accrued from the use of antitoxin are in any way comparable with those resulting from vaccination. The latter, moreover, is a trustworthy preventive of small pox, and the immunity thus engendered lasts for many years, whereas the immunity against diphtheria afforded by previous inoculation with antitoxin is doubtful, and probably of short duration. Collective statistics leave no doubt in the minds of unprejudiced persons as to the extreme utility of the antitoxin treatment of diphtheria, and we agree with the lecturer that a medical man who, in presence of an undoubted case of diphtheria, abstains from the use of this agent, incurs responsibility little short of criminal. When Mr. Bousfield talks, as he is reported to have done at a subsequent "interview," about reducing the mortality from diphtheria in his parish from 15 to 5 by antitoxin70

thereby saving 100 lives annually, we can only suggest that he is counting his chickens before they are hatched. We cannot, moreover, follow the lecturer when, with an enthusiasm which is explained but not justified, by his not being a specialist, he goes on to assert that, in time, every infectious disease will be stamped out by the aid of antitoxins, a doctrine which, even if true, would render sanitary legislation supererogatory. Lastly, quite unintentionally no doubt, the lecturer threw an unmerited slur on the vaccine at present in use by expressing a hope that it would be possible to provide an absolutely pure culture of vaccinia free from the possibility of its containing the germ of any other disease. precisely what is claimed for glycerinated lymph, and though the possibility of septic contamination can never under any circumstances be absolutely obviated, it may safely be asserted that we have now reached a point approximating the irreducible minimum of risk in this direction.

Vulvitis in Children.

DR. ROBINSON'S paper on "Vulvitis in Children," the discussion on which, before the Obstetrical Society, was reported in our last number, opens up a very vexed question. This condition is tolerably common and often presents great and even painful interest from a medico-legal point of view. The causes of vulvitis as given in the text-books are numerous and varied, but according to the author bacteriological examination of the discharges in a large number of cases revealed the presence of an organism indistinguishable from the gonococcus in 76 per cent. This result is so startling that, rather than accept the otherwise inevitable conclusion, one is tempted to question the diagnostic value of the presence of the diplococcus in question. In the crowded dwellings of certain classes of the population it is conceivable that gonorrheal infection may be readily spread by the use of a common chamber utensil or, between children, by digital exchanges. These discharges, however, are met with in all classes of society, though doubtless they are more common among the unwashed, overcrowded, ill-nourished offspring of the poor. Clinically the evidence is opposed to the gonorrheal origin of the affection unless we concede that gonorrhea in the young runs a much milder course than in the adult, no proof whereof has as yet been The inguinal glands are very rarely furnished. enlarged in children suffering from vulvar discharge, and there is a singular absence of conjunctival complications, though as the irritation is productive of itching one would have expected frequent transference of the virus. Observed cases of unquestionable gonorrhæa contracted by children as the result of rape do not support the assumption that the disease is milder in them than in adults, and we are driven to challenge the identity of the organism upon which the author based his conclusions.

Dr. Lawrie on the Plague.

IT cannot truthfully be said that the evidence so far given before the Plague Commission in India has

thrown any further light on the etiology and mode of dissemination of this fell disease. As to this, however, we shall be better able to form an opinion when we are in possession of the report which will not be accessible for a long time to come. The most sensational statements have been made by Dr. Lawrie who, with a recklessness and impetuousness peculiarly his own, has fulminated against the Haffkine system of preventive inoculation. Now this remedial and preventive measure is on its trial and, on the whole, the tenor of the reports that have so far reached us of the results obtained are decidedly in its favour. It behoves us, therefore, to preserve an open mind and to avoid jumping to a conclusion one way or the other. Dr. Lawrie is in no better position to form a trustworthy opinion at this juncture than anyone else, and common sense would have suggested a prudent reticence in respect of his opinions, although he would have been fully justified in alleging all facts that had come to his knowledge. It is not his facts-for these were remarkably few-which we object to, but his inferences and ex parte statements, based on sweeping generalisation and random assertion. This is not the spirit in which scientific questions of this magnitude should be approached, an attitude of dispassionate scepticism best becomes the investigator, not violent denunciation and hasty generalisation. Dr. Lawrie ought to have learned this lesson from his misguided precipitation in the matter of the malarial parasite, the existence whereof he boldly denied, but the existence whereof has since been almost universally admitted. Dr. Haffkine is engaged in carrying out a gigantic experiment on data which have been thoroughly worked out, and it is unjust to him and to his coadjutors to declare urbi et orbe that the treatment is a dangerous delusion.

A Wicked Fraud.

An inquest was held a few days ago at Modbury, near Plymouth, on the body of a man who had been treated by a quack, of the name of Roberts, for diabetes. This unqualified person advertises that he can cure cancer and diabetes, and it was in consequence of these advertisements that the deceased had consulted him. A sum of £2 10s. was paid at the first interview, in exchange for which the deceased was given a number of powders, ascertained by analysis to consist of common salt, soon after taking which he became comatose and died. The jury found that death was due to natural causes, but added a rider to the effect that the treatment was absolutely useless, and "was nothing but a fraud." Roberts was cautioned as to his future conduct, but we trust the matter will not be allowed to rest there, for he has impudently infringed the Apothecaries' Act, and there ought to be no difficulty in obtaining a conviction.

Charges of Malpraxis.

A DRAWBACK, of no mean degree, to the medical profession, is undeniably the annoyance caused by dissatisfied patients bringing charges of malpraxis against its members. In the present day, unfor-

tunately, these charges seem to be of more frequent occurrence than used to be the case, and almost without exception the legal reports in the newspapers show them to be absurd and without any foundation. No doubt in some cases an ignorant and poor person having some grievance of the kind, backed up by an enterprising but not over scrupulous solicitor, thinks that a medical man is "good game" to make an attack upon. The proceedings are consequently commenced; notice is given to the doctor, all his patients hear of the action pending against him, and thus his troubles and annoyance increase until the trial. jury, possibly without leaving the box. nonsuit the plaintiff, and virtually intimate that the action should never have been brought. result, in a measure, may be consoling to the practitioner, but the experience is one which costs him dear. Apart from the unavoidable anxieties attending such an ordeal, he also soon probably finds that there will be no chance of recovering his costs of the trial, owing to the plaintiff being a person without In the past, medical men have frequently found themselves in this predicament, and no one can deny that it constitutes a hardship, the occurrence of which should not be legally possible. In regard to these cases of alleged malpraxis the law of the land is—and it is only common-sense law—that a medical man cannot be held responsible for a mere error of judgment, provided that he uses reasonable skill and care. Unless this were the case, medical practice would become well-nigh impossible, and the result of it would be that the public would be left to look after their own illnesses and accidents.

The Wark Case.

THE MEDICAL PRESS AND CIRCULAR was the first of the professional journals to call in question the verdict and sentence on this unfortunate man Since the appearance of our comments, the whole press of the country has been with us, and have quoted our views, in protest against injustice in the name of justice and law, and the final denouement has done but little to quiet matters. At the trial before Judge Phillimore, Lieut. Wark was sentenced to death for a crime he could not possibly have committed, and concerning which there was distinct evidence to show that he was not guilty. All this has now been altered, and he has been sentenced for a crime for which he was not tried, for it is absurd to contend that three years' imprisonment is a punishment for murder—the only crime he was charged with. What with biassed judges and weakkneed Home Secretaries, well—the ways of justice are past finding out.

Vivisection in India.

THE anti-vivisection party have succeeded in discovering another mare's nest, in which the absurdity of their protestations is again weefully exposed. They have alleged that the Pasteur Institute to be shortly founded in India will be entirely opposed to the religious sentiment of the natives, so much so, that it may be expected to cause another Mutiny.

An anti-vivisectionist must be a person possessing a lively imagination, otherwise he would not be qualified to maintain the tenets of his party, and to say that a Pasteur Institute in India will cause a mutinous outbreak among the natives is just the kind of lively imaginative excrescence likely evolved from an anti-vivisectionist's mind. Unfortunately, however, for the anti-vivisectionist party the facts as to this allegation are entirely against them. The Pasteur Institute in India will be founded and supported by the Nizam of Hyderabad, a prince of great and acknowledged intelligence who is fully conversant with all the objects that the Institute will seek to attain. Moreover, as it has been pointed out, experiments upon animals are not repugnant to the feelings of the natives. As a matter of fact, they have infinitely less objection to experiments being performed on dogs, rabbits, and cats than they have to Englishmen eating beef. Despite the fact that the cow is a sacred animal among the natives, the slaughter of cattle in India has, up to the present, not been accused of having caused a mutiny.

The Vaccination Act and the Payment of Vaccination Officers.

HARMONY has not reigned among all boards of guardians upon the subject of the payment of the vaccination officers under the new Act. The minimum fees allowed by the Local Government Board have in some instances been refused by them, and this has been followed by the guardians giving them a month's notice to terminate their appointments. We doubt, however, whether this step will lead to the solution of the difficulty, inasmuch as it is scarcely likely that other medical men will be prepared to accept the offer of unremunerative fees.

The Sanitation of Belfast.

Some months since we noticed from week to week the barbarous condition of the second city in Ireland as regards sanitation. We took our information from the debates in the local papers not supposing that the reality could be worse than the disorganisation therein reported, or that the sordid greed of the jerry builder, encouraged by the Corporation, could be more disgraceful to the latter body than was represented. Our contemporary, the Lancet, has, however, dragged the foulness of the city and its public health organisation into the light in a series of reports by its special commissioner, published in its issues of December 31st and previous weeks, and, if these reports are to be trusted, it is clear that Belfast is nothing better than a sort of Sodom and Gomorrha, in a sanitary sense, and that no milder remedy than fire and brimstone would be effectual treatment for its condition. Considerations of space preclude our giving quotations from these reports except the

concluding paragraph, which runs as follows:—
After all these investigations I must confess to being overwhelmed with a deep sense of despair. When even such easy trifles as the cementing of a closet-pan on its syphon trap are so generally neglected, though the presence of typhoid fever in

the houses should have caused all such defects to be promptly detected and remedied, it is impossible to hope with much confidence that the great and sweeping measures of sanitary reform urgently needed will be efficaciously applied. Is it likely that an administration which, at any rate in the past, has displayed such crass incapacity and has been guilty of such palpable life-destroying neglect will ever be able to produce a Hercules capable of cleaning out these Augean stables? Does this not rather suggest that a higher and outside authority should interfere, so that the law shall at last be enforced, and that the work of efficient sanitary supervision shall be no longer neglected?

A New Opening for Quacks.

QUACKS and the compounders of patent medicines desirous of pushing business, and anxious for a cheap advertisement should make a point of being enrolled upon a coroner's jury. At an inquest last week a juryman showed that a coroner's court could be most successfully utilised in the attainment of these objects. The inquiry was held for the purpose of ascertaining the circumstances of the death of a man who had as the evidence showed, suffered for two years from pulmonary phthisis. Before the verdict was given of "natural death," a juryman observed, "I should like to say a few words on consumption. I can cure consumption, whether in the first stage or the last, and I can cure spitting up of blood as well. If any gentleman suffers from it, I shall only be too happy to cure him." The juryman subsequently assured the coroner that he cured a gentleman of consumption after the latter had spent a fortune in trying various medical men. This was undoubtedly a startling piece of information, to come from a bootmaker, which the juryman stated was his occupation. Unfortunately, however, this bootmaker's philanthropy did not extend so far as to inform the Court regarding the precise composition of his remedy. An expectant British public thus has its appetite for information whetted in a remarkable manner without any chance of having it appeased. The bootmaker has clearly intimated that he will not divulge his secret, and from the free and extensive advertisement which he has just received through the coroner's court, he is now probably making arrangements for a very large increase in business.

Tropical Diseases at Netley.

The letter in the *Times* of January 6th from Dr. John Anderson, of the Seamen's (*Dreadnought*) Hospital, respecting the cases of tropical disease which are usually under treatment at Netley, unmistakably indicates that if the scheme for a school of tropical medicine be carried into effect Netley Hospital is the only place where the clinical material available for the purpose could be forthcoming. Dr. Anderson's figures very effectually dispose of the suggestion found a school of tropical medicine at the branch hospital of the Seamen's Hospital Society at the Albert Docks. We trust that Mr. Chamberlain will see the futility and inexpediency of maintaining his sanction to this suggestion. It would

simply be a waste of public money to attempt to organise the undertaking in this particular form, and if this scheme is still persisted in the matter should be brought under the notice of the House of Commons early in the ensuing Session.

The Increase of Lunacy.

THE county authorities of Somerset, in common with a good many others, are beginning to find that the problem of providing accommodation for the increasing number of lunatics is becoming a very serious one. With respect to the Yeovil Union, for example, it was recently stated that the increase in lunacy during the past twenty years amounted to 200 per cent. In order to meet the demand for more accommodation an asylum was built at Cotford, near Taunton, and this institution was only recently opened. But arrangements, we believe, are already being made with a view to enlarging it. With the present rate of augmentation of the lunatic population throughout the country, the time seems to be approaching when the sane persons outside of the asylums will be required to devote a large measure of their earnings merely to the maintenance of lunatics. There is no doubt that one of the most serious aspects of this question is the enormous burden which will eventually fall upon the country of making due provision for the care of the insane.

The Abortion Charge Against a Nurse.

CHARGES of criminal abortion continue to bulk largely in the courts of law. The most recent case is that of the London nurse, Birmingham, who has been committed by a coroner's jury for trial upon a charge of wilful murder for causing the death of a woman in Oxford Street by an illegal operation. At the present stage of the proceedings it would obviously be unfair to offer any comment upon the case. However, the offence with which the prisoner is charged has other aspects, which may be touched upon with something more than a featherweight and generalising pen. First and foremost, how is it that nurses and other unqualified abortionists secure their victims? The answer to that pertinent question is undoubtedly that for the most part they carry on their illicit traffic through the medium of advertisement in the public newspapers. Now, the police have shown most commendable zeal in following up and bringing home offences of the kind. Will they not in future go to the root of the matter and prosecute for inciting to felony the newspapers that admit this abominable class of advertisement? One successful action of this sort, we firmly believe, would do more to check abortion than the yearly hanging of a score of miscreants caught and convicted here and there among the multitude. What an opportunity for a strong Home Office administra-

Dr. George Foy, Dublin, delivered a lecture last week before the Irish Pharmacists' Assistants' Association, upon the subject of "Anæsthetics." The lecture was profusely illustrated by original manuscripts, cartoons, and old-time engravings.

The X Rays in War.

LAST week a valuable contribution to the literature of military surgery was made at the Rontgen Society by Major Battersby, R.A.M.C., the Medical Officer recently in charge of the Rontgen ray department in the Soudan expedition. After the battle of Omdurman the rays were successfully applied in 20 cases, where other methods of examination failed. The carrying out of the work was attended by great difficulties, chiefly on account of the heat, varied from 100 degrees to 120 degrees F, in the shade. However, the resulting photographs, although hardly on a level with ordinary exhibition work, nevertheless answered every surgical requirement as regarded both diagnosis and exact localisation. The coils were packed in boxes cased in felt, which was constantly wetted, so as to keep the contents cool. The necessity of these steps is clear when we reflect that the insulating agent of the coil is paraffin. The generation of electricity was effected by means of a tandem bicycle, connected with a dynamo, from which the storage batteries were charged. Altogether Major Battersby triumphantly proved the absolute value of this new method of diagnosis in military work.

Death Under Ether.

An inquest was held on the 12th instant at Kingston-on-Thames on the body of a man, aged 52, who had succumbed to the effects of ether administered for the purpose of an operation. It transpired that he had been suffering from bronchitis and heart disease. Dr. Woolley, who gave the anæsthetic, said he had only (?) administered about two fluid ounces of ether when the patient vomited and respiration ceased, and all efforts to restore animation failed. Deaths from ether are tolerably rare, at any rate in this country, possibly because chloroform is still the favourite anæsthetic with the many. In any event, ether is generally held to be contra-indicated in cases where there is any tendency to bronchitis, and if, as stated, the deceased suffered from this disease, some surprise may be felt that chloroform was not preferred.

An "Appendicitis" Controversy.

THERE is no doubt that in many respects our nomenclature of diseases is far from correct. Nevertheless, who can dispute the force of fashion or custom in this matter? A name is given to a particular disease, and it comes at once into general use; then some one finds that it is etymologically quite erroneous, and presses for the substitution of a new and, perhaps, more correct word. Despite, however, the strenuous efforts made in this direction, nothing ever comes of them, for it is quite impossible to undermine the popularity which general use has gained for the first, though admittedly erroneous. term. Apropos of this subject, some controversy is now taking place with regard to the word appendicitis—described as a verbal monstrosity. It has been suggested that ecphyaditis is the best name for the disease, but we question whether, even from the

first, such a term would ever have commended itself for popular professional use. But epityphlitis suggested by Küster, of Marburg, is better, although one cannot see that it has much to recommend it in comparison with appendicitis. As a matter of fact, appendicitis is a useful, even if it be an incorrect term. Its meaning is well understood, and it is not likely to be superseded.

Epithelioma of the Uvula.

PRIMARY epithelioma of the uvula is a very rare affection, and for this reason a case of the kind, reported by Dr. W. Downie in the current number of the Scottish Medical and Surgical Journal, is of special interest. The patient was a blacksmith fifty-six years old, and when he came under observation his uvula was greatly enlarged, and the greater part of its surface ulcerated; it was also hard and firm on palpation, and slight manipulation caused the surface to bleed. No lymphatic enlargement could be detected. The disease was diagnosed to be epithelioma, and the appendage was at once excised, under cocaine. Healing of the wound took place in a few days, and since then, now seventeen months ago, the patient has enjoyed perfect health without any signs of recurrence. scopical examination of the growth confirmed the diagnosis, but the literature of the subject only contains the record of one other case of primary malignant disease of the uvula.

Aortic Aneurysm and Cardiac Hypertrophy.

HITHERTO there has been a curious difference of opinion as to whether or not aneurysm of the aorta entails hypertrophy of the left ventricle. Seeing that the aneurysm is virtually a dilatation of part of the vascular system, it is not obvious why hypertrophy should result, and the statistics based on an examination of the post-mortem records at St. Bartholomew's Hospital, recently compiled by Dr. Calvert seem to show that hypertrophy is, at any rate. not the rule in aneurysm. Of 124 cases of aortic aneurism, hypertrophy of the left ventricle was only found in 47, and much the same proportion was discovered by Dr. L. Barlow at St. George's (5 out of 13). We may therefore dismiss from our minds the idea that there is any essential connection between the presence of aneurysm and left ventricle hypertrophy. Even when hypertrophy is present, it by no means follows that it is caused by the aneurysm-Aneurysm is usually consequent upon atheromatous degeneration, and atheroma is specially prone to exist in the subjects of high arterial tension, i.e., patients suffering from some form of kidney mischief, an affection intimately associated with marked hypertrophy. Of course, if the aneurysm be so situated as to interfere with the closure of the aortic valves, the resulting regurgitation will lead to hypertrophy of the ventricle, but even then the aneurysm is not the direct cause of the hypertrophy. The old idea was that the loss of elastic recoil, consequent upon an atheromatous condition of the large vessels, threw more strain upon the heart, and led to muscular hyperplasia, but this very hypothetical view is not borne out by actual observation, and while hypertrophy may conceivably cause aneurysm, it has now been conclusively shown that aneurysm does not cause hypertrophy.

Nugent's Borrowed Diploma.

THE man Rowland, who recently practised as a medical man at Barking, has been sentenced to three years' imprisonment, for manslaughter, and three for personating a registered practitioner, to wit, one Nugent, the two sentences to run concurrently. For the prisoner it was urged that, although the Medical Defence Union had challenged his qualifications so far back as 1895, yet no proceedings had been undertaken by the General Medical Council. We fancy that this delightfully candid statement will be read with mixed feelings by those members of the Council, who have hitherto sat in the seat of the scornful, and played the part of laisser faire with haughty contempt of the outside world. Where is now the purity of the Register, the maintenance of which we were always taught was the highest and most sacred duty of that august body? This extraordinary case is bound to come before the Council next session, and it is to be hoped that the medical profession will insist on sifting the matter in broad daylight. No good can come of half measures.

The New Spectacle Sellers' Diploma.

HERE is what the Spectacle Makers' Guild and its professional agents have brought us to. The annexed advertisement appeared in a recent issue of the Daily Mail: - H. L - -, F.S.M.C. (Sight Specialist), Certificated Optician by Examination, . . . Street. -'s treatment of Defective Eyes is entirely successful. Headache, Neuralgia, Pain in the Eyes, due to Eye Strain, Permanently Cured. Examined, Sight Tested, and all information Free of Charge." It may be recollected that, when we entered our emphatic protest against the prostitution of the function of that ancient brotherhood by the wholesale selling of so-called diplomas in spectacle-making. the Master of the Guild assured us that if it were found that any diplomate was using his parchment to attract medical or surgical business the company would at once withdraw the diploma. We now invite the Master to fulfil his promise, as there can be no question that this advertiser seeks to utilise his document for such purpose.

Six Months in Gaol for Selling Bad Meat.

AT last the reign of justice, reasonable and evenhanded, appears to have been established in the kingdom of the Metropolitan magistracy, and, indeed, more or less also of their provincial brethren as regards the punishment of bad meat offences. For many years past the futility of mere fines inflicted upon this class of offender has been insisted upon in the columns of THE MEDICAL PRESS AND CIRCULAR. Even now there is too great a tendency to substitute a heavy money penalty in place of imprisonment, but we are glad to see an increasing number of sharp and

salutary sentences recorded Last week, for instance a Cambridgeshire butcher was haled before the London Guildhall Police Court charged with sending to the Metropolitan market unsound pork, which was described in evidence as "in a filthy condition." The defendant was notorious for his bad meat transactions, and had previously suffered imprisonment for a similar offence. On this occasion he was very properly sentenced to hard labour for six months. From the point of view of preventive medicine it is difficult to over-estimate the necessity for the maintenance of a high standard in the food supplies of the community.

Lunacy, the Poor-law, and Delirium Tremens.

Two occurrences were reported last week in Metropolitan Poor-law Institutions, things that would simply be impossible under any strong and enlightened system of Local Government Board control. The first was a protest of the Chairman of the St. Olave's Board of Guardians against the detention of an epileptic boy, æt. 9, in a lunatic ward where he had remained for five months, in spite of the protests of the Medical Officer. Where are the Lunacy Commissioners, where is the Local Government Board Inspector, where are the necessary formalities preliminary to confining any person among lunatics? The second incident was the treatment of a patient suffering from delirium tremens, who, according to the newspaper reports, was admitted to Poplar Infirmary, put first into a straight jacket, and then into a padded room, where be died. No one who is acquainted with the modern practice of medicine will doubt for a moment that a patient under such circumstances would not be placed under the best conditions for recovery. Indeed, the use of such brutal and obsolete methods of restraint at once condemns the institution which has resort to them. Tales of deaths in padded cells have before this come from East End infirmaries. Again we ask, where are the responsible central administrators of the Poor-law?

Tea Cigarettes.

THE physiological effects of smoking cigarettes made of tea are very graphically described by a The feeling in the mouth, he says, is peculiar, but so is the taste of an ordinary cigarette to the beginner. It is not, he adds, as disagreeable as might be supposed, but the result in a tyro is to bring about a sense of thickening of the head, and a disposition to take hold of something or to sit down, symptoms which have also been noted in the early stiges of nicot ne poisoning. If the trial be persevered with the thickening feeling gives place to one of intense exhilaration, which however only lasts as long as the smoke-in fact, it ends in smoke. The after-effects are said to be too dreadful, the agony of the opium smoker being but a shadow to that of the victim of tea cigarettes. There is utter loss of appetite, despondency, with more or less muscular tremor, and it is some hours before the repentant sinner begins to revive. If any misguided young person takes to smoking tea after this warning it will not be our fault!

THE Henley-on-Thames Board of Guardians have resolved to memorialise the Government to repeal the Vaccination Act. In coming to this decision one of the guardians stated that it was the most rotten Artwhich he had ever known.

PERSONAL.

Dr. H. Macnaughton Jones has been re-elected President of the British Gynæcological Society for the ensuing year.

DE. ROBERT BARNES has been elected honorary President of the Gynæcological Congress which is to take place at Amsterdam in August

H.R.H. PRINCESS CHRISTIAN will distribute the prizes to the London Companies of the Volunteer Medical Staff Corps on Friday, January 27th.

DE. MACFIE CAMPBELL, Consulting Surgeon to the Northern Hospital, has been elected President of the Liverpool Medical Institution.

Mr. Cadge, F.R.C.S.E., has given another £10,000 to the Norwich Hospital, this donation making £20,000 with which he has endowed that institution.

DR. GEORGE PLUNKETT O'FARRELL, Inspector of Lunatic Asylums, received last week the honour of a Knighthood from the Lord-Lieutenant of Ireland.

THE knighthood previously announced in this journal as about to be conferred on Dr. Hermann Weber, was personally bestowed by her Majesty at Osborne on Saturday last.

DE. HENRY E. ARMSTRONG, Medical Officer of Health for Newcastle-on-Tyne, has been elected a corresponding member of the Royal Medico-Chirurgical Academy of Madrid.

MR. TIMOTHY L. WELFORD, the oldest member of the profession in Reading, died there last week, aged 86. At the time of his death he was the senior magistrate on the local bench.

Dr. C. R MARSHALL, Assistant Downing Professor of Medicine in the University of Cambridge, has been appointed Professor of Materia Medica at University College, Dublin.

Dr. Hill, Master of Downing College, and Vice-Chancellor of the University of Cambridge, has been reappointed University Lecturer in advanced Human Anatomy till Michaelmas, 1903.

Dr. C. P. O'CONNOB, of March, Cambs., has been presented with a silver salver on the occasion of his marriage, subscribed for by nearly 300 employes of the Great Eastern Railway engaged in that district, as a token of esteem.

DE. MURRELL, Physician to the Westminster Hospital, has been appointed Examiner in Medicine, "with special reference to Materia Medica and Therapeutics," in the University of Glasgow, vice Dr. F. D. C. Phillips, whose term of office has just expired

DE. WYLLIE, who was appointed to carry on Professor Fraser's duties in the Edinburgh Royal Infirmary during his stay in India, has, we have been informed, gathered round him an almost record number of students, attracted by the excellence of his teaching.

DR. MANUEL TAPIA Y SERRANO died a few days ago of pulmonary trouble, contracted by excessive work in his laboratory. As a pathologist and bacteriologist he was known throughout Spain. He was a member of the Royal Academy of Medicine of Madrid, and of the Society Los Escolares Médicos.

Dr. C. H. Martin, of Mobile, Atalanta, whose death is announced, was one of the best known of Southern surgeons. He was Medical Director of the Army Corps commanded by Leonidas Polk during the inter-States war in America. In 1875 the University of Pennsylvania conferred on him the honorary degree of LL.D.

Ws understand that Surgeon-General J. A. Woolfryes, C.B., will be appointed Honorary Physician to the Queen, in succession to the late Surgeon-General A. Smith. He entered the Army Medical Service fifty years agò, and has seen much fighting, being mentioned in despatches and receiving several medals and clasps for services rendered.

SURGEON-COLONEL PRINGLE, who died at Blackheath last week, was one of the few survivors of the Cawnpore massacre, all his brother officers being killed, but he escaped through being called off to attend the wounded elsewhere. He retired on pension in 1883, and has since been engaged in local and philanthropic work in the neighbourhood in which he resided.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE CONSUMPTION CAMPAIGN.—The rapidly growing opinion that the community might combat the ravages of the destructive little bacillus of tubercle with some measure of the success which has followed the measures taken to lessen the effects of typhus, typhoid, and small-pox, if only facilities for proper treatment and the spreading of a true conception of the manner in which the organisms may be baulked, or their effects removed, if treated early encugh, is holding out promise of bearing practical fruit within a short time in Edinburgh. The Town Council has appointed a committee to investigate and consider the question One of the suggestions made is that the new City Hospital for infectious cases, nearly completed, and with greater accommodation than will for some time be called for, for the reception of cases of the common zymotic diseases, should be in part set aside for the reception and treatment of consumptive cases. Its site, high above the sea on the side of Craig Lockhart Hill, one of Edinburgh's many heights, favours the idea of treating patients with this disease by the pure air method. On an average 42 medical beds in the infirmary of Edinburgh's medical wards are occupied each year, day and night, by tuberculous cases, if the total number and the duration of their stay in hospital be expressed in terms of beds occupied per annum. Many are in the early stages which are so often curable or inhibited by proper surroundings, to which the general wards of a hospital cannot aspire.

THE LATE DR. W. H. MURRAY.—After an illness lasting several months, W. H. Murray, M.D Edin. (M.B., C.M.. 1874), died last week at his residence in Galashiels, at the early age of 46. He was one of the best known practitioners in the Scottish Borders. In addition to an extensive practice, Dr. Murray found time to interest

himself in public affairs, both municipal and political. He was one of the leading Conservatives in Galashiels.

THE CASE OF LIEUT, WARK.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Though perhaps some of your medical readers may demur, I trust you will permit me to call the attention of the public to the vast progress that medical science has made among the educated classes during the last forty years. Indeed, even at a later date, the man would have been ridiculed who predicted that before the end of the century not only the Home Secretary and the judges, but even our common jurors would know more about the most abstruse branches of the science than the doctors themselves. Just forty years ago occurred the famous case of Dr. Smethurst. It revealed to the public the scandalous deficiences of the Home Office at that period. The jury may, indeed, have been in advance of the doctors (or of some of them) but the Home Secretary was literally unable to form any opinion for himself as to the cause of Miss Bankes's death, and was driven to the painful expedient of calling in a physician—the late Sir Benjamin Collins Brodie-to decide the question. Sir Benjamin, however, could not decide it. He merely said "I doubt," and by a strange misapplication of the legal principle that the prisoner is entitled to the benefit of the doubt (which in reality means that he is entitled to the benefits of such doubts as the judge in his charge may consider irremovable) the prisoner was actually set at liberty. Nor was the action of the Home Office in the Maybrick case in 1889 free from objection. The doctors were divided in opinion as to the cause of death. The jurors, with their more advanced knowledge of toxicology (under the direction of a judge whose ironical disclaimers of any knowledge of that science concealed a skill far exceeding that of Sir Benjamin Brodie) entertained no doubt whatever. Yet the weak Home Secretary actually consulted other doctors on the subject, and arrived at the astonishing result that the cause of death was actually doubtful! But by an important advance over his predecessor he naturally and justly decided that under the circumstances the Crown was clearly entitled to the benefit of this doubt. The Wark case, however, marks a new era. Drs Briggs and Paul had an advantage over the judge, the jury, and the Home Secretary in having made a careful post-mortem examination of the body which the others had not seen Yet notwithstanding this disadvantage, the judge, the jury, and the Home Secretary all saw clearly that death had resulted from an illegal operation which the doctors with their inferior knowledge of obstetrics had failed to discover. It will be recollected that the Home Secretary was the Minister in attendance when the heir to the throne w s born, and I have no doubt that his knowledge of the subject proved of great advantage to the accoucheurs on that occasion. The lesson of the Wark case is that doctors should keep abreast of the age—that they should not be ignorant of the proofs of poisoning or violence, which are known to every man on the jury (at least as soon as he has heard the judge). Every physician or surgeon should recollect that he is placed in the witness-box for the same purpose, that according to the judge the Maybrick jury had been impanelled—that of solving an intellectual problem of great difficulty. If he cannot solve that problem he should not enter the witness-box at all. Why should he pester the public with doubts that never enter the heads of men who know far more about medicine and surgery than he does-too much about it indeed to make it worth their while to take out their diplomas? We do not want doubt. We want certainty. We can to a certain extent combat the unwillingness of the doctors to give us certainties by giving the benefit of their doubts to the Crown. We know that the proofs of murder are present in the body and that

nothing but the ignorance or negligence of the doctors prevented these from being detected. If doctors cannot give us something better than doubt we had better dispense with their evidence altogether. It is their business to know, and a confession that they do not know is an admission that they do not understand their business. It is fortunate for the public that we have a Home Secretary who cares as little for the doctors as he cares for the Chief Justice. He is as superior in medical knowledge to the former as he is in legal knowledge to the latter.

I am Sir, yours truly, GARDEZ BIEN.

CENSURABLE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see that the dispenser to the Stockport practitioner who recently killed a woman by putting fifty grains of morphine into her medicine, the dose whereof he inadvertently changed from teaspoonfuls to table-spoonfuls, has been declared "censurable," while his employer was censured for having written his prescription in an incomplete form. There does not appear to have been any excuse for so grotesque an error. All the culprit had to say in extenuation of his conduct was that he was "confused" by neuralgic and domestic trouble. We all know what that means, and the question of diagnosis may safely be left to your readers.

The point I wish to call attention to is the inadequate protection to human life which the law affords. In any other country than this such an incident would, of a certainty, have entailed upon the delinquent a term of imprisonment, and his employer would have been mulcted in heavy damages in a civil court. Here they are both simply declared "censurable."

A medical man who employs an unqualified disp nser incurs a heavy moral responsibility, but it appears to me to savour of 'infamous conduct"—a point which I commend to the notice of the General Medical Council.

I am, Sir, yours truly,

OBSERVER.

THE CENTENARY OF NITROUS OXIDE AS AN ANÆSTHETIC.

To the Editor of The Medical Press and Circular. Sir.—With your permission I would call the attention of your readers to the fact that this year is the centenary of the discovery of the anæsthetic properties of nitrous oxide gas. The discovery was made in the laboratory of the Hotwells Hospital, Clifton, Bristol, which Dr. Thomas Beddees built, with the pecuniary aid of Mr. Edgeworth and Mr. Wedgewood, to test the therapeutic values of "factitious" airs.

It was probably the last week in November, 1799, that Mr. Humphrey Davy, as we learn from his letter to Mr. Davies Gilbert, made his celebrated statement:—"As nitrous oxide in its extensive operation appears capable of destroying physical pain, it may probably be used with advantage during surgical operations."

Wordsworth, Southey, Coleridge, the younger Priestley, James and Gregory Watt, Wedgewood, Count Rumford, and many other distinguished individuals, watched over the birth of modern anæsthetics, and of all these Davy alone suggested the practical application of the discovery.

alone suggested the practical application of the discovery. One of the first to inhale the gas was Anna, the wife of Dr. Thomas Beddoes, Sister of Maria Edgeworth, the novelist, and daughter of Honora Sneyd, who married Richard Edgeworth in 1773.

Three years previously Miss Sneyd rejected the suit of John Andre, who was shot as a spy by George Washington's orders in 1780, for whom the whole British Army went into mourning, and of whom a tablet, in Westminster Abbey, tells: He "fell a sacrifice to his great zeal for his king and country, when employed in an important and hazardous enterprise."

I am, Sir, yours truly,
GEORGE Fov.

January, 1899.

Literature.

PLAYFAIR'S MIDWIFERY. (a)

A NEW edition of such a standard work as this, calls more for welcome than criticism. Dr. Playfair writes not only with wide scientific knowledge, but with the indefinable quality of wisdom which renders his text-book of great value to practitioners, while the easy flowing style and the marginal notes at each paragraph make it appreciated by the student. The present edition has been largely revised and partly re-written, and some new plates and wood-cuts added, Several of the older wood-cuts might, however, have been altered with advantage, as they depict the obstetrician performing various operations, such as version and the application of forceps, with his coat and shirt sleeve down to his wrist. It is surely indispensable, from the point of view of aseptic midwifery, that the forearms should be bare and well disinfected, and it would impress this on the student's mind if the plates represented the sleeves well

But on the score of asepsis most English text-books on midwifery seem to be woefully behindhand, and we fear that any student who told his examiner that he would douche the uterus with a Higginson's syringe would score badly, yet this is what Dr. Playfair recommends, and we can find no reference to the infinitely superior syphon douche. Again, in view of the excellent results at the Rotunda Hospital from plugging in accidental hæmorrhage, it is strange that this treatment is not even mentioned in discussing this most dangerous complication. But even when one differs with the author the charm of his style disarms an opponent, and one can only offer congratulations on the continued popularity of his treatise.

POCKET DICTIONARY OF HYGIENE. (b)

In this neat little pocket dictionary the authors have given concise and up-to-date information on a great number of matters relating to hygiene, and though the little work is primarily intended as a pocket companion for medical officers, sanitary inspectors, and those interested in hygiene, there is little information in it that would not be of use and interest to every householder.

As might be expected the preventive measures that should be adopted in the case of infective disease have received a large share of attention, though not to the neglect of other matters. If we were to single out a particular section for special mention, it would be the monograph on "Water," in which the more important considerations involved in securing a safe supply are ably set forth. The advice given as to the general procedure to be adopted in the care of patients suffering from zymotic diseases is thoroughly sound and practical, and the student will find the tables and other data given at the end very convenient for reference. The little book is evidently intended for hard wear, as it is bound in flexible leather, and the paper, though thin, is exceed-ingly tough to handle, and the moderate price at which it is issued (2s. 6d.), should place it within the popular

RAMSAY'S ATLAS OF EYE DISEASE. (c)

Or special diseases none are so dependent, for their delineation and understanding, as those of the eye and of the skin. Outlines with appropriate shading are sufficient to portray anatomical conditions and surgical affections, and even most medical diseases, but there is so much in the way of diagnosis to learn from the tints of colouring of an inflamed iris, or the minute distortions of a disintegrated cornea or lens, that the visus eruditus

cannot be attained otherwise than by prolonged observa-tion of multitudes of bad eyes. The diagnostic faculty can be acquired only upon the observation of hundreds of patients, but the acquirement can be greatly assisted by the study of a well illustrated volume, such as Dr. Ramsay's. The portrayal of eye diseases by the agency of the lithographer is attended with great difficulty, because, no matter how well selected the subjects may be, no matter how accurate the draughtsman and the colour artist, the printer is sure to overdo the colouring. It is, in fact, impossible to get in the half-tones and other minutiæ on the printing press, and, for this reason, all illustrations of eye disease are too blatant, and leave something to be desired. The only thoroughly satisfying pictures of eyes affections which we have ever seen are those of James Wardrop, of Edinburgh, published in 1808. Wardrop was a professional artist before he became an eye doctor, and, while he wrote an excellent resume of what was then known of eye diseases, he was forced to illustrate them with his own hand, and that of his daughters who were also professional artists. He had copper plate outlines printed in his book, and he and his assistants coloured them with the brush, with both the tuctus eruditus and the visus eruditus, and every copy of the book is used was thus, actually, from the artistic brush of the expert him elf. We advise any ophthalmic specialist to pounce upon a copy of Wardrop s book if one can be found.

Of the illustrative atlasses of eye disease which we have seen Dr. Ramsays is one of the best, the subjects of illustration being, on the whole, well selected and, generally speaking, well depicted. Photogravure is availed of in many instances, and it is quite satisfactory in depiction of ptosis, ædema palpebrarum, and paralytic conditions, in which outline is everything and colouring is nothing, but we suggest that it was a mistake to seek to convey the idea of interstitial keratitis, or strumous ophthalmia or Jacob's ulcer, or chronic glaucoma, by a method which does not admit of colour illustration, On the whole, as we have said, we feel that Dr. Ramsay has' done good service in the publication of his atlas—that it will prove to be a first-class clinical book and a great help to the working practitioner, and, moreover, does credit to the enterprise of the author who has thus shown his familiarity with the multitudinous forms

of eye disease.

WEBSTER'S DISEASES OF WOMEN. (a)

Or the making of books there is no end, and we regret that in the volume before us we are unable to find any reason for its issue. As is usual with the Scotch schoolof gynecologists much of the book is taken up with anatomy, which, though fully recognising its extreme importance, we think could better be found in Quain or Gray. Speaking generally, the book is a poor imitation of Hart and Barbour's "Manual of Gynæcology."

In "points to be observed before passing the sound" no mention is made even of douching the vagina, much less sterilising it, and yet this is one of the first lessons now impressed on the student; also it is a retrograde step to find a modern gynæcologist advocating the side position in examinations with fingers anointed with vase ine or oil and introduced under the clothing.

Shall we ever see the last of that dreadful Zwanck's

pessary which is here figured as usual?

We are pleased to note that the author is apparently a believer in asepsis from the chapter on antisepsis and asepsis, but we would point out at the same time that considering his book is published in 1898, this chapter should have been brought up to date, this branch of medical science moves rapidly, besides it is not only in operative work that asepsis is indicated, probably there would be less occasion for resorting to this if more care were exercised during examinations per vaginam, &c, The credit of introducing ventro-fixation is due to Koeberle and Olshausen, and not to Howard Kelly, though we would wish to give him every credit for perfecting the operation. In conclusion, we regret to say though the book is clearly printed and well got up

(a) "Diseases of Women." By J. C. Webster, Pp. Edlnburgh: Young J. Pentland.

⁽a; "A Treatise on the Science and Practice of Midwifery," By W. S. Playfair, M.D. London: Smith, Elder and Co. Ninth Edition. 1998.

b) "Perket Dictionary of Hygiene." By C. T. Kingzett, F. I. C., and D. Homfray, B.Sc. London: Bailliere, Tindall and Cox. 1898.

(c) "Atlas of Diseases of the Eye." 48 full-page plates of the eye in colour and Photogravure. By A. Maitland Ramsay, M.D., Professor of Ophthalmology, St. Mungo's College, Glasgow. Glasgow: MacLehose and Sons. Quarto, pp. 194; plates, 48.

the author has failed to establish a claim when there are so many better, sounder, and more up-to-date books availahle

WARING'S OPERATIVE SURGERY. (a)

WE have looked into this book with great care, and have subjected it to the test which an operator may regard as the most severe, namely, that of using it frequently as a book of reference about matters on which the memory of even the most busy surgeon requires to be refreshed. It is pleasant to be able to report in its favour in a very unqualified way. Whether regard is had to its matter, text, or illustrations, it will be found alike satisfactory in all. It is a full, and yet a very concise, compendium of up-to-date operative work, clear without being tedious, and exact without waste of words. Whether as an educational instrument for students, or as a book for hasty reference by informed but busy operators, we can strongly recommend its use. It deals thoroughly with recent questions and methods, and with the exception of some minor matters, such as vasectomy, is really a complete compendium of the subjects it treats of; and it is right to remember that this operation may be regarded by the author as not yet being one of established reputation. The operation given for the cure of various veins, is certainly not the best, and we have seen results from the very simple proceeding described first by Sir Thornley Stoker in the Dublin Journal of Medical Science (March, 1895) superior to those of any other method.

GUBB'S MIDWIFERY FOR MIDWIVES AND MONTHLY NURSES. (b)

This little work, which does not extend beyond a hundred pages, has, we are told, been compiled specially in view of the requirements of candidates for the certificate of the Obstetrical Society of London. That it will cover these requirements we can readily believe, indeed, we may congratulate the author upon not having kept too strictly to the somewhat narrow limits of the schedule. The amount of knowledge which a candidate midwife possesses on passing her examination by no means represents all that she may usefully acquire, not so much for the purpose of trespassing upon the field of activity which properly belongs to the medical man, but in order that she may understand better when to requisition skilled assistance, and also in order that she may be in a position to render intelligent aid to the doctor in operating procedures. If the midwife of the future will only conform to the advice here given there can never be any friction between her and the neighbouring doctors, and for her sake we trust she will. A midwife, who has carefully studied and thoroughly grasped this manual, will certainly be in a position to distinguish between a normal and an abnormal labour, and she will be prepared to deal with the ordinary emergencies of the lying-in room as they occur, and to cope with such as are within the scope of her duties; while in respect of the others she need never be at a loss to know what to do pending the arrival of the doctor. The subject is dealt with in plain English, and the text is copiously illustrated. It is printed in large type, and is altogether very easy reading. What more can the most fastidious student ask?

EARL'S "LIVING ORGANISM." (c)

THE author, recognising that biology has profoundly influenced current thought, and that biological discoveries are influencing philosophy, has attempted to lay down the true foundations of the study and to show how far conclusions may be drawn from them and how far speculations may be made. He defines the science of

(a) "Manual of Operative Surgery." By J. Waring, M.B., B.Sc. Lond., F.R.C.S.; Demonstrator of Operative Surgery, St. Bartholomew's Hospital, &c., &c. Edinburgh: Young J. Pentland, 1898.
(b) "A Handbook of Midwifery for Midwives and Monthly Nurses." By Alfred S. Gubb, M.D. (Paris), &c. Aberdeen: Mr. James Bisset. 1898.
(c) "The Living Organism." an Introfuction to the Problems of Biology. By Alfred Earl, M.A. London: Macmillan and Co. 1898. Pp. xiii.-271.

biology as "a certain body of connected knowledge, which is derived from the observation of living objects

and from reflections based on that observation."

An important caution is: "Ideas derived from our own experience of life are too readily transferred to other forms of life," and the author warns his readers that the utmost we are entitled to do is to infer for the lower forms of life a nebulous state of something resembling feeling.

The author first gives a general outline of the scheme of biology, taking methods of alimentation as a guide; then deals with classification, surroundings, form, energy, development, sensation, &c., showing in each the permanent limits to knowledge.

On the whole, the book is interesting and suggestive, and it may keep eager biologists from too strongly advocating theories; but its real value is not to the biologist, but to those who are applying biological methods to other branches of research.

BOTTONE ON X-RAYS. (a)

This little volume is one of many that have appeared since Prof. Röntgen's famous discovery of the X-rays. Its author has contented himself with giving a short account of the principles involved and the apparatus needed in the work of practical radiography. Wisely, as it seems to us, he has kept out of the field of medical and surgical work, into which some non-medical writers have recently shown a tendency to plunge with more or less disastrous results. He appears to have worked chiefly with a Wimshurst influence machine, a source of electricity that has hardly received the attention it deserves at the hands of practical Röntgen ray workers in this country. Among the illustrations is a useful one illustrating the effects of over-exposure and under exposure of the sensitive plate by comparison with a third that has been properly timed. The book will be found useful to those who want a short summary of the subject, but is not full enough to be of much service to the advanced worker.

Laboratory Aotes.

READY-MADE SOUPS.

THE triumph of antisepsis by sterilisation is nowhere seen and appreciated to better advantage than when applied to articles for use in the culinary department. We have been afforded an opportunity of examining and testing various preserved soups prepared by the well-known West end caterer, Mr. Venant Benoist, of 36, Piccadilly, among them being "Real Turtle Soup" and "Consommé de Volaille." We first tested their keeping properties, and are enabled to state that, even in the absence of any special precautions as to temperature, &c., they were perfectly edible two months after receipt thereof, and provided high quality soups not differing, from a gastronomic point of view, from the freshly-made articles. So far as our experience of real turtle soup goes, the special properties and savour which make this la reine des potages are found in their entirety in the products contained in these sealed glass receptacles. Being preserved and sterilized in glass there is no risk of contamination by the action of organic acids on a metal container, and analysis yielded no trace of any chemical preservatives. As the preparation of these soups in the ordinary way is a somewhat tedious and difficult procedure in the average kitchen, we are pleased to refer our readers to a means of obtaining them on less onerous conditions.

THE death is aunounced from Paris of Dr. Dumontpallier, who has acquired considerable notoriety, and even fame, as an authority on diseases of the nervous system more particularly in respect of the phenomena of hypnotism.

Medical Aews.

Liverpool Medical Institution.

At the annual meeting, held Thursday, January 12th, the following list of office bearers, members of Council, and Committees was adopted:—President, W. Macfie Campbell; Vice-Presidents, R. S. Archer, H. Harvey.

*A. Bernard, and *T. B. Grimsdale; Hon. Treasurer, James Armstrong; Hon. General Secretary, J. M. Hunt; Hon. Secretary to Ordinary Meetings, W. Thelwall Thomas; Hon. Librarian, W. Permewan; Council, F. H. Barendt, E. A. Browne; R. Caton, F. Johnston, Leslie Roberts, Arthur Wallace, "William Alexander. "R. A. Bickersteth, "T. M. Dawson, "J. C. Davey, "J. Burns Gemmel, and "J. J. O'Hagan; Auditors, "H. Harvey and Gemmel, and "J. J. O'Hagan; Auditors, "H. Harvey and "C. J. Macalister; Pathological and Microscopical Committee, J. H. Abram, F. H. Barendt, R. A. Bickersteth, R. Boyce, A. W. Campbell, F. C. Larkin, C. J. Macalister, G. P. Newbolt, F. T. Paul, and C. S. Sherrington; Journal Committee, Hon. Sec Ordinary Meetings, Hon. Sec Pathological Section, "F. T. Paul, F. H. Barendt, T. B. Grimsdale, C. G. Lee, C. J. Macalister, G. P. Newbolt, and W. Parmewen, "These marked ("did not held the and W. Permewan. Those marked (*) did not hold the same office last yerr.

Medical, Sickness, and Accident Society.

THE annual monthly meeting of the Executive Committee of the Medical, Sickness, Annuity, and Life Assurance Society, was held at 429, Strand, London, W.C., on the 30th ult. There were present Dr. De Havilland Hal in the chair, Dr. J. B. Ball, Dr. M. Greenwood, Dr. Walter Smith, Dr. Alfred S. Gubb, Dr. J. W. Hunt, Dr. W. Knowsley Sibley, and Dr F. J. Allan. The amounts presented showed that the business of the year 1898 would be no exception to the rule of prosperity which has attended the operations of the Society since it started in 1884. A large sum has been paid away during the twelve months as sickness allowance to the members incapacitated by illness or accident, but the total is well under the amount expected and provided for, and the year's working shows a considerable increase of the funds of the Society which now amount to over £120,000. Prospectuses and all information on application to Mr. F. Addiscott, Secretary, Medical, Sickness, and Accident Society, 33, Chancery Lane, London, W.C.

Chelsea |Hospital for Women

BARONNE DE HIRSCH has contributed £200 towards the £4,000 required for the new Nurses' Home, the enlargement of the operating theatre, and other improvements contemplated in connection with this institution.

New Coroner's Court.

In accordance with the policy of the London County In accordance with the policy of the London County Council, a new coroner's court was recently opened for public use at Hammersmith. It is described as the largest and most complete building of its kind in the metropolis. By an arrangement of passages the jury will only have to view the bodies through glass windows, and besides post-mortem rooms, it is fitted with a disinfecting-house, shell-house, and laboratory, together with a special mortuary for infectious cases. The total with a special mortuary for infectious cases. The total cost of the building, which is lighted throughout with electric light, is £3,743.

British Gynsecological Society.

THE annual meeting of the Society was held on January 12th, 1899, the president, Dr. MacNaughton-Jones, in the chair. The following officers and Council for the year 1899 were elected:—
Hon. President.—R. Barnes, M.D., F.R.C.P. (London).

President.—H. MacNaughton-Jones, M.D., F.R.C.S.I.

(London).

Vice-Presidents.—G. G. Bantock, M.D. (London), A. E. Cordes, M.D. (Geneva), G. Elder, M.D. (Nottingham), R. H. Hodgson, M.D. (London), F. Bowreman Jessett, F.R.C.S. (London), J. Macpherson Lawrie, M.D. (Weymouth), J. J. Macan, M.D. (London), R. Milne Murray, M.D. (Edinburgh), R. D. Purefoy, M.D. (Dublin), F. F. Schacht, M.D., B.A. (London), W. Travers, M.D., F.R.C.S. (London), and Professor Hector Treub, M.D., Amsterdam) M.D. (Amsterdam).

Treasurer.—J. A. Mansell-Moullin, M.D. (London).

Council. - W. Armstrong, M.R.C.S. (Buxton), N.

Whitelaw Bourns, M.D. (London), Professor Murdoch Cameron, M.D. (Glasgow), John Campbell, M.D., F.R.C.S. (Belfast), G. Roe Carter, M.R.C P.I. (London), A. Donald, M.D. (Manchester), T. Eastes, M.D. F.R.C.S. (Folkestone), M.D. (Manchester), T. Eastes, M.D. F.R.C.S. (Folkestone), F. Edge, M.D.. F.R.C.S. (Wolverhampton), C. H. Gage-Brown, M.D. (London), H. Bellamy Gardner, M.R.C.S. (London), C. Godson, M.D. (London), H. S. Howell, M.D. (London), J. Furneaux Jordan, F.R.C.S. (Birmingham), Skene Keith, M.B., F.R.C.S.Ed. (London), Christopher Martin, M.B., F.R.C.S. (Birmingham), T. Morton, M.D. (London), W. H. Newnham, M.B.Cantab. (Clifton), Professor A. W. Mayo-Robson, F.R.C.S. (Leeds), C. H. F. Routh, M.D. (London), W. Slimon, M.D. (London), F. H. C.S. (Leeds), C. H. F. Routh, M.D. (London), W. Slimon, M.D. (London), E. T. Smith, L.S A. (London), Heywood Smith, M.D. (London), R. T. Smith, M.D. (London), and D. Thomson, M.D. (London).

THE MEDICAL PRESS.

Editors of Journal.—F. F. Schacht, M.D., B.A. (London), Arthur E. Giles, M.D., B.Sc. (London), and

J. J. Macan, M. D., M.A. (London).

Hon. Secretaries.—George E. Keith, M.B. (London), and Arthur E. Giles, M.D., B.Sc. (London).

and Arthur E. Giles, M.D., B.C. (London).

The President gave his Annual Address on "Gynæcological Lessons of the Past Year." A conversations followed, at which some 150 Fellows and visitors were present. Recitations by Mr. M. B. Spurr. and selections of vocal music by the Misses and Mr. Isidor de Solla were much appreciated. Some new and interesting gynæcological instruments were shown by the President, including Dr. Kolighar's oversting gystæcope. Dr. including Dr. Kolischer's operating cystoscope, Dr. Doyen's levier piace for producing hamostasis by pressure and crushing, in vaginal and abdominal hysterectomy, Professor Schauta's ligature tightener for securing ligatures in difficult positions in the pelvis; and various other gynæcological appliances.

Dr. M. K. HARGREAVES, of Wimbledon, was last week the defendant in an action for malpraxis brought by a carpenter who claimed damages on the ground that after an accident he had been treated by the defendant for fracture of the tibia, whereas the fibula was also broken. Evidence was given in plaintiff's favour by Dr. David Findlay, who asserted that extension ought to have been employed to prevent displacement, but after hearing professional testimony on the other side the jury unhesitatingly gave a verdict for the defendant.

Society for the Relief of Widows and Orphans of Medical Men.

At the quarterly court of directors of this Society, held on Wednesday last, Dr. Stamford Felce, V.P., in the chair, one new member was elected, and the deaths of seven reported. Among the deaths the directors had to regret those of three old and valued members, viz., Sir William Jenner, V.P., Dr. Hare, and Dr. Munk. One application from a widow was received, and a grant at the rate of £50 per annum made. It was resolved to distribute the sum of £1,216 10s. among the fifty widows, ten orphans, and six recipients from the Copeland Fund. The expenses of the quarter were £77. A Christmas present of £551 had been given to the widows and orphans on December 18th, and a special grant of £20 had been made to a widow suffering from malignant disease.

An unqualified person called Thomas Owen Davies was last week sued under the Apothecaries' Act on the ground of the illegal practice of medicine, and a penalty of £20 and costs was inflicted, it being intimated, however that the penalty would not be pressed for if the defendant would undertake not to repeat the offence.

West London Medico-Chirurgical Society.

A DISCUSSION on "The Treatment - Medical and Surgical—of Acute Inflammation of the Vermiform Appendix" will take place at the next meeting of the Society on Friday, February 3rd, at 8.15 p.m., in the Society's Rooms at the West London Hospital, Hammersmith, W. It is expected that a large number of members and visitors will be present. Any medical man is invited to attend as a visitor if not already a member of the Society. The discussion will be opened by Dr. Seymour Taylor and Mr. McAdam Eccles, and, among others, the following have promised to take part: Dr. Donald Hood, Mr. C. B Keetley, Dr. Stanley Smith, Mr. L. A. Bidwell, Dr. H. A. Caley.

Motices to

Correspondents, Short Letters, &c.

Correspondents requiring a reply in this column are par ticularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves ' Reader." "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

M. N. O.—The marriage rate for London shows a steady increase, being higher in 1897 than for twenty-two years previously. Curiously enough, there is far from being a corresponding increase in the birth rate, which has progressively fallen for the last thirty years, and now stands at 30. The cause of this diminution is probably social rather than physiological, and it is a manifestation of a tendency which appears to be characteristic of existing civilisation.

Dr. OGILVIE.-We will endeavour to comply with your request in the near future.

Dr. P.—We are unable to publish your communication, partly by reason of its inordinate length, partly by reason of its excessively personal nature.

Dr. MAYGRIER (Paris).—The receipt of Prof. Maygrier's clinical lecture on "The Treatment of Fissures of the Nipples," from our French correspondent is hereby acknowledged with thanks.

THE CONVICT COLLINS.

"Sir," writes T 428, "I find it stated that Dr. Collins has been transferred from Chelmsford to Portland. Sir, this is an error. Dr. Collins was transferred to "partmoor. He is doing well as a member of No. 38 party (Med. Officer's party). All prisoners in No. 38 get full diet and full marks, and the supposed-to-be lightest labour in the prison. I left Collins and the party last week "My esteemed correspondent, says the Sun, is, as you see, an ex-convict, and has just done the best part of seven years' penal servitude.

JENNERIAN LITERATURE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It has been suggested to me that the members of the medical profession might give valuable help in educating the public in the cause of vaccination by allowing specimens of Jennerian literature to lie on the tables of their waiting-rooms, where they might be seen by their patients and others. The Jenner Society will be happy to supply such literature to anyone who will apply for it.

will be happy to supply such interactive to anyone who will apply for it.

I am glad to find, from communications I am increasingly receiving, that the members of the profession are beginning to take much more active part in this good work than they have hitherto done, by giving lectures and addresses on the subject, by correspondence in the public papers, and by joining in debares on it. I shall be pleased to give any assistance in this direction to any who may desir it.

I am, Sir, yours truly,

FRANCIS T. Bond, M.D.,

Hon. Secretary, Jenner Society.

The Jenner Society, Gloucester, January 3rd, 1899.

[Dr. Bond sends us a large number of pamphlets which bear eloquent testimony to the good work done by his Society. Every medical man should have copies of these, which he can distribute among his patients.—Ed., M. P. & C.]

Meetings of the Societies and Tectures.

WEDNESDAY, JANUARY 18TH.

Clinical Lecture

ON

DYSPEPSIA OR GASTRIC DILATATION?

Delivered at the Westminster Hospital.

By WILLIAM MURRELL, M.D., F.R.C.P., Physician to, and Joint-Lecturer on Medicine at the Hospital.

THERE is no doubt that many patients who are supposed to be suffering from chronic dyspepsia are in reality the victims of dilatation of the stomach and could readily be cured by an operation. The symptoms are similar and might easily be incorrectly interpreted. Moreover, in these cases, patients often come with a ready made diagnosis, and when a patient says that he is suffering from indigestion it too often happens that a prescription is written without any detailed investigation into the nature of the symptoms and without any examination into the condition of the abdominal organs. There are, of course, many varieties of dyspepsia, such as nervous dyspepsia, gouty dyspepsia, and alcoholic dyspepsia, but the most common form is that due to gastric insufficiency. In these cases there is not only a diminished and inadequate secretion of gastric juice, but the motor activity of the organ is impaired. It is common enough in people who lead a sedentary life, take but little exercise, and work their brains inordinately.

The symptoms of gastric insufficiency and of gastric dilatation or gastrectasis have many points in common, although they differ in matters of detail. In the first place, there is the pain or discomfort which in cases of dyspepsia usually comes on soon after taking a meal. It is usually referred to the epigastric region, but may extend over the whole of the abdomen, and even to the interscapular region or some distart part of the body. It is not an acute pain, such as we get in biliary, renal, or intestinal colic, but is of a dull, aching character. It may persist for hours, especially after a full meal, or when food is taken of an especially indigestible character. It is usually accompanied by considerable depression of spirits, and the patient displays a marked disinclination for either mental or physical exertion. There is often drowsiness, with a teeling of oppression, and the patient, if disturbed, is apt to show signs of irritability. Sometimes the pain is of a burning character, and an acid bitter fluid, which sets the teeth on edge, regurgitates into the mouth. The patient calls it heartburn, and says that he has an attack of acidity. It is not in reality due to excess of hydrochloric acid in the stomach, but arises from the lactic acid formed by bacterial decomposition of carbohydrates or from butyric acid and other products of fermentation. The pain of gastric dilatation is of a somewhat different character—is not experienced immediately after food, is rarely acute, is not associated with pyrosis or eructations, and is independent of the kind of food taken. It is purely mechanical in origin, and is

promptly relieved by vomiting or by syphonage. Vomiting is not a constant symptom of dyspepsia, but many patients intentionally make themselves sick for the sake of the relief which the evacuation of the contents of the stomach affords. When, however, there is vomiting it usually takes place soon after the indigestible meal has been taken. In dilatation of the stomach the vomiting is long delayed. For instance, in a case recently under my care, the patient dined at 2 p.m., and vomited at 7 or 8 o'clock in the evening. Impairment of appetite is common to both conditions, and in gastrectasis it is especially capricious. In one of our cases the patient had long ceased to take meat, and lived almost entirely on milk and tea and bread and butter. In dyspepsia the evacuations are usually solid, dry, and hard, and they may be light in colour, whilst in dilated stomach they are usually shrunken and hard. Thirst is nearly always a prominent symptom of gastrectasis, and may be so pronounced as to lead to a suspicion that the patient has diabetes. The distended stomach is incapable of absorbing the fluid poured into it, and the patient is dry and parched. This symptom has often to be relieved by copious enemata of water, which the rectum absorbs with avidity. Loss of flesh is another prominent symptom of dilated stomach, and the patient becomes rapidly emaciated. One of our patients on admission weighed 104 lbs., and another only 72 lbs. The temperature is subnormal, and the patient is feeble and constantly complains of chilliness. The urine is constantly complains of chilliness. scanty and contains triple phosphates in abundance. The vital condition is low, the pulse is weak, the face is pale and pinched, and the patient is capable of but little exertion. The spirits are depressed, and sleep is often disturbed by distressing dreams. Headache, tinnitus, vertigo, and other nervous phenomena are complained of, and the patient often presents indications of auto-intoxication due to the retention of unassimilated food, a condition resembling that so often seen in cases of long continued constipation.

Dyspepsia and gastrectasis have many symptoms in common, but there are many points of difference. The delayed vomiting, the thirst and the rapid emaciation in a case supposed to be dyspepsia, should excite a suspicion of the existence of a dilated

Any stomach is dilated whatever may be the capacity when its propulsive power is so diminished that the passage of the food is abnormally delayed. There is no standard stomach for a given size of hody, and the capacity of an adult's stomach in a condition of health ranges from 9 ozs. to 60 ozs. The average is from thirty-five to forty ounces, and anything over sixty ounces is abnormal. Gastrectasis is usually associated with some form of pyloric obstruction, possibly malignant, but more probably due to contraction of the cicatrices of gastric ulcers. The ordinary treatment of gastric ulcer is notoriously inadequate, and many patients who have been confined to bed for six weeks or more, and who have been religiously fed on peptonised food or by rectal enemata, return in a few weeks with a recurrence of all their old symptoms, and in a large proportion of cases, with superadded gastrectasis. Gastric ulcer

is the common starting point of dilated stomach, especially in young women, but it may arise from exceptional causes, such as torsion due to dislocation, adhesions to neighbouring structures, such as the liver or gall-bladder, and even to enteroptosis. This enteroptosis or visceroptosis is a very curious condition, the term being applied to those cases in which the various abdominal organs have become displaced from their normal position. As this displacement is nearly always in a downward direction, the term "dropping of the viscera" has been applied to it, and it is analogous to the "falling of the womb" with which we are familiar in women. Enteroptosis was originally described by Glénard in 1885, and is often spoken of in accordance with the very prevalent but by no means commendable custom of naming every pathological condition or group of symptoms after some particular individual, as Glénard's Disease. This displacement is especially apt to occur in cases of dilated stomach associated with obstruction of the pylorus, and it is both a cause and an effect. The stomach is usually displaced to the left, and the enlarged pylorus if it can be detected by manual examination is found to be well over the left of the median line. Normally the pylorus is opposite a point just below the riphister-num and just outside the parasternal line. This form of displacement of the stomach is, however, rare, and for all practical purposes dilatation of the stomach as a chronic affection is due either to malignant disease of the pylorus or to the contraction resulting from the cicatrices of gastric ulcers. Gastrectasis may, however, assume a more acute form, and is met with in the course of rheumatic fever and pneumonia, or as a complication of phthisis, diabetes, and other diseases. The enlarged abdomen of rickety children is in some cases due to this condition.

Chronic dilatation of the stomach occurs chiefly in women, and usually in women of middle age. When it is met with in persons over fifty it is commonly due to or associated with malignant disease of the pylorus. The physical signs are of the greatest value in arriving at a diagnosis. It is often said that it is difficult to map out the stomach by percussion, but I have not found this to be the case, and we have never had to resort to the expedient of distending the viscus by carbonic acid, formed by the administration first of an alkaline carbonate and then of an acid. The "splash" sign is not always obtainable, but when present it is an indication of considerable importance. Syphonage may be employed for diagnostic purposes, but it is not essential. In many of our cases the diagnosis was so clear that there was no necessity for putting the patient to the pain and discomfort of introducing a tube.

The treatment of cases of dyspepsia usually presents no difficulty. If there are from time to time failures it is from the neglect to recognise certain elementary facts which are familiar enough to everyone who has had much experience of out-patient work. In the treatment of dyspepsia it is necessary to remember that alkalies increase acid secretions and decrease alkaline secretions, and that acids increase alkaline secretions and decrease acid secretions. This is the key-note to the situation. Then, again, many prescribers have no facility in manipulating their bitter-tonics. They order some one particular member of the group with which they are familiar and ignore the others. If they prescribe gentian they prescribe gentian always, and never use its congeners quassia, calumba, chiretta, and so on. Then again many people have very little practical acquaintance with the value of oil of cajeput in the treatment of dyspepsia accompanied by flatulence. In a well-known book on diseases of the stomach I find a long list of antifermentatives, including resoscin and Beta-naphthol, but not a word about

cajeput. Three drops of oil of cajeput on a piece of sugar or on a crumb of bread taken frequently is worth all the others put together. It is not only antiseptic but it is agreeable to take. Glycerin, too, is an excellent remedy, and a teaspoonful in a wine glass of water flavoured with a few drops of lemon juice will in many cases effect a speedy cure. Very often I use equal parts of glycerine and glycerine of borax. A useful prescription is boro-glyceride, half a drachm, glycerin half a drachm, spirit of chloroform, fifteen minims, syrup of lemon, half a drachm, and water to an ounce. Capsicum is most useful in alcoholic dyspepsia and in the gastritis of drunkards. Minim, or two minim doses are ample, but the tincture must never be given in an effervescing mixture or you may blind your patient. The custom of stimulating the mucous membrane of the stomach by the application of tincture of iodine is a good one. I order ten minims of tincture of iodine in an ounce of water, with half a drachm of glycerine. It is administered before food, and the patient is directed to roll over from side to side once or twice so as to diffuse it evenly all over the lining of the stomach. It gives rise to no pain but only to a pleasant sensation of warmth, and I have never known it do any harm even when there has been reason to suspect the existence of ulceration. Bichromate of potassium is another drug which it is impossible to ignore. Prof. T. R. Fraser, of Edinburgh, to whom we are indebted for the introduction of this remedy has shown that it is capable often in a short time of removing the entire group of symptoms encountered in dyspepsia especially anorexia, pain, nausea, vomiting, and gastric tenderness. It should be administered fasting in doses of from one-twelfth grain to one-sixth grain three times a day either in solution or in the form of a pill. The solution may be conveniently flavoured with syrup of tolu or syrup of orange, and the pills are best made up with kaolin ointment. In cases of gastric ulcer the results are just as favourable as in simple cases of dyspepsia with the exception that in acute gastric ulceration with hæmatemesis the bleeding from the stomach is not checked. Probably the worst fault of all in the treatment of dyspepsia is the custom of prescribing pepsin without explicit directions as to the kind or make of pepsin which is to be dispensed. There are pepsins and pepsins; some are excellent whilst others are so inactive as to be practically useless. The estimation of the comparative value of different preparations of pepsin, although simple in theory is by no means easy in practice. The essential action of pepsin is proteolytic —the conversion of proteids into pertones—and this is taken as the test of the value of the specimen. The observation may be made on fibrin or egg-albumin, but the latter is more convenient. The eggs must be quite fresh and should be boiled in a uniform manner. The best way is to boil the water first, and then put the eggs in altogether, and let them boil for ten minutes. If a shorter time is allowed, the white will not separate from the yolk nicely and cleanly. Fifteen eggs will yield 7,000 grains of coagulated albumin, or perhaps a little less. The best test is the weight of albumen which one grain of pepsin will digest in four hours in eight ounces of 1 per cent. hydrochloric acid of sp. gr. 1 150 at a temperature of 38 deg. C. Some time ago I tested all the pepsins in the market, English as well as foreign, and the difference in activity was so startling that now I never prescribe pepsin without indicating the particular make required, and I never prescribe any special form of pepsin without previously ascertaining for myself exactly what it will do. Another mistake commonly made with respect to pepsin is to give it in doses which are too small and are powerless to exert any beneficial action.

The treatment of dilated stomach is a much mor

serious matter. Electricity is useless, and massage often fails to give good results. Lavage or syphonage is useful, but it is a slow, tedious, and disagreeable process. To have to wash out your stomach every night and morning is a serious addition to your other toilet requirements. The best plan is to have an operation, and to get cured at once. You remember a woman recently in the Hospital, the cubic capacity of whose stomach was eight pints. She had been under treatment for six months, and for the greater part of that time had had syphonage, but in spite of this she was steadily losing ground. I remembered that in cases of relaxed scrotum, I had seen a large fold of useless tissue removed in order to leave a serviceable bag in which to contain the testicles, without the necessity for constantly wearing a suspensory bandage, so I asked Mr. Spencer if he could not take a reef out of the woman's stomach, or, at all events, run in a few tucks so as to reduce its size and improve its motor power. He suggested that what I wanted was a combination of pyloroplasty and gastrorrhaphy —pyloroplasty to enlarge the pylorus, and gastrorrhaphy to reduce the stomach to its normal size. The words seem formidable, but the operation itself in his skilled hands fortunately presented no difficulty. The pyloric end of the stomach and the pylorus were found to be involved in a mass of scar tissue, with inflammatory bands outside. The bands were first divided between two ligatures, and then the mass of scar-tissue in the pylorus by means of longitudinal incisions. The pyloric aper-ture was stretched, and tucks were made in the wall of the stomach by interrupted sutures running along the whole of the anterior surface so as to reduce it to the normal size. The operation lasted over two hours, chiefly in consequence of the unsatisfactory condition of the patient, but she made an uninter-ruptedly good recovery. The temperature never rose above 100 4 F., there was no vomiting, and practically no pain or discomfort. Three weeks after the operation she was up and about, and could take meat, fish, pudding, bread and butter, jelly and eggs, without the slightest difficulty, and she had gained a stone in weight. The publication of this successful case (a) brought other patients desirous of obtaining relief, many of them being sent in especially with a view to operation, and Mr. Spencer now performs gastrorraphy almost every week. We are not yet in a position to publish statistics, but I may say that so far we have not had a single failure. As an illustration of the benefit to be derived from this mode of procedure, I will give you an outline of a case still in the hospital, which presents many features of interest. The patient, a single woman, set. 48, was sent in under my care by Dr. Stonely Hill, on November 30th, 1898. She is a cook by occupation, and had suffered from flatulence for ten years, but with this exception had fairly good health until nine months ago, when the flatulence became worse, and she suffered from vomiting and pain referred to the epigastric region. The pain was not acute, but was of a gnawing character. At this time she had dinner at 2 p.m., and a cup of tea and a slice of bread and butter at 4 p.m. The pain always came on between 6 and 7 p.m., and was followed by The vomited matter consisted first of her dinner and tea mixed, and then of white frothy fluid. The pain was relieved by vomiting, and did not return until the same time the next day. Her appetite was extremely poor, but even if she took no food all day she vomited large quantities of the white frothy fluid in the evening. About six months ago these symptoms increased in severity, the pain radiated all over the abdomen, and extended to the inter-scapular region.

The flatulence and discomfort were more severe violent, and she suffered vomiting was more greatly from thirst. greatly from thirst. She rapidly lost flesh until she was reduced to 5 st. 2 lbs., and was unable to follow her occupation. On admission she was carefully examined but no tumour could be detected in the abdomen. The stomach was percussed out without difficulty. The highest limit of gastric resonance was the sixth rib in the nipple line, whilst its liver boundary extended to the subcostal line. Its greatest curvature extended in relation to the sixth, seventh, eighth, ninth, and tenth ribs to the subcostal line, whilst the lesser curvature was in the epigastric region the gastric note merging into a hyper-resonant area extending into the umbilical and right hypochondriac regions. The area of the stomach, however, varied from time to time, and not infrequently the gastric note could be detected as low as the umbilicus, The "splash" could be obtained, although not always. There was no doubt as to the diagnosis, and it was obviously a case of gastrectasis. The fact of the patient g been three years under the absence of hæmatemesis observation practically excluded malignant disease and ulcer of the stomach. We were so certain about the nature of the case that we did not think it necessary to pass a tube into the stomach. Mr. Spencer decided to operate at once. The stomach was enormously distended, and there were old scars in the neighbourhood of the pylorus, which was attached by thickened bands to the under surface of the liver. The mode of procedure adopted was that already described, the operation lasting an hour and a quarter. The highest temperature was 100.4 degs., and on the third day the patient was able to take food by the mouth, and ten days later she was taking pounded meat and fish.

The prognosis in the case on which Mr. Spencer operated yesterday was considered to be less favourable. The following was the opinion given on admission: The patient is a woman of middle age who some years ago had a severe attack of gastric ulcer during which she vomited large quantities of blood. For the last thirteen weeks she has suffered from severe pain in the abdomen, coming on about half-anhour after each meal and followed in about two hours by vomiting. When she lies on the left side there is a dull aching pain, which is quite independent of the pain excited by food. She loses flesh rapidly, and is greatly emaciated. The stomach is dilated, and its greater curvature extends well below the umbilicus. In the right hypochondriac region and in the upper part of the umbilical region a thickening can be detected both by palpation and by percussion. She has probably malignant disease of the pylorus, which may have attacked the site of old cicatricial tissue. Gastrojejunostomy will probably have to be performed. This unfavourable prognosis fortunately turned out to be incorrect. Directly the abdomen was opened it was seen that there was no tumour. The stomach was constricted some little distance above the pylorus by old cicatricial tissue, which had resulted from the healing of an ulcer, but there was no malignant growth. The stomach was adherent to the under surface of the liver, and there were firm bands of attachment running between the stomach and the duodenum. The bands were divided between ligatures and the stomach was opened, but it was not thought necessary to run in tucks. You will have an opportunity of watching the progress of the case, which I have no doubt will be favourable. This patient affords a good illustration of the fact that a condition presenting all the clinical features of cancer of the stomach may turn out to be non-malignant, and may be relieved by a comparatively simple operation.

I am told that the operation of gastrorrhaphy is "unsurgical," but that is a matter of perfect indifference to me as long as it saves the lives of my patients. I am informed that it is just as absurd as it would be to treat stricture of the urethra by making tucks in a man's bladder. I do not see the analogy, for the bladder is simply a receptacle for urine, whilst the stomach is a secreting organ. Moreover, in our cases we always stretch the pylorus in addition to reducing the size of the stomach. But granting the analogy, I hardly think that our critics would propose dilating the pylorus by passing a bougie into the rectum.

My points are that many cases supposed to be chronic dyspepsia are in reality cases of dilated stomach, and that they can be cured by an operation.

Paris Clinical **L**ectures.

TREATMENT OF FISSURES OF THE NIPPLES BY ORTHOFORM.

By PROF. MAYGRIER, Paris.

[FROM OUR FRENCH CORRESPONDENT.]

FEW affections exist for which so many remedies have been proposed as that of fissure of the nipples. This apparent abundance in the rapeutics is in this case, as in almost every other, a proof of our poverty in respect of a really effectual medication. It appears to me, on the other hand, superfluous to remark how regrettable it would be to seem to despise this little lesion, which, although temporary and in general benign, is none the less extremely painful and frequently constitutes a point of entry to infection of the mammary gland; infection, needless to state, serious to the mother and dangerous to the infant. In most cases maternal nursing is jeopardised, and that is a result which it is the duty of the medical attendant to avoid if possible.

Antiseptic dressing, wet, dry, or astringent dressing, cicatrising varnish, local anæsthetics, all have been tried with variable results; tincture of benzoin, tannin, collodion, &c., nothing has proved definitely and constantly effective. I may add, however, that nothing is so variable as the conditions in which the treatment is habitually carried out, for the fissures may be more or less numerous and more or less

infected in each case.

Up to the present, the alcohol dressing recommended by M. Budin, has given us the best results; but the painful phenomenon remains none the less, and we know that this fact has a real importance. Cocain used by Herrgott in this special point of view has not given all that was expected from it; even though washing of the nipple be insisted upon before presenting it to the infant, the cocain constitutes a dangerous poison for the latter, as its existence is at the mercy of a negligent mother. Further, cocain is not devoid of action on the physiology of the lacteal secretion. Various practitioners, among others, Guenel of Nantes, who published an instructive observation on the subject, state that they have witnessed a decrease and even a complete suppression of the milk under the employment of cocain. my colleagues used it twice in private practice to suppress the secretion at the period chosen for weaning the child, and with success. This fact is not so surprising when it is considered that the stimulation of the papillæ of the nipples in the act of nursing plays a manifest $r\delta le$ in the function of the gland; to suppress its excitability by an anæsthetic closes the door to an essential reflex. It was with these facts in mind that I thought of employing orthoform, which had

already given proof of its anæsthetic properties in its local application to cutaneous or mucous excoriations in the hands of Klaussner, Hirschbuch, Ginestons, Kallemberger, Neumayer, Yonge, &c.
Without devoting time to the chemical history of

orthoform already given by all the above authors, I will simply remind you that it is the methylic ether of para-amidomela oxy-benzoic acid, a synthetic product belonging to the same chemical family as cocain and different eucains described sometime ago. Orthoform is a crystalline yellowish power, insipid and inodorous, scarcely soluble in water, very soluble in alcot ol, and especially so in ether, and by no means toxic. Einhorn applied in one week fifty grammes of orthoform to a large ulcer of the leg without provoking any symptoms of poisoning; more recently Soulier and Guinard, of Lyons, made a special study of the poisonous proportions of the drug and found it to average to one gramme per kilogramme of the weight of the body. Orthoform was introduced by its inventor as an antiseptic, but Lichwitz and Sabrayés made experiments with it and declared it to have but a moderate action in this direction, consequently it would not be well to place too much reliance on it and neglect the ordinary rules of asepsis. Can it by itself constitute a vehicle of germs and carry with it infection? In a word, is it necessary to submit it to disinfection before using it P I do

The most interesting point in the history of ortho-form is its local analgesic action. It is very powerful, since the deepest burns become under its contact almost immediately painless, and Blondel was able to practise curettage under its application without causing much suffering. Bernoud and Garel, of Lyons, have used it with success to relieve dysphagia caused by tuberculous ulceration of the pharynx, and in certain small operations in this region. Yonge eased by its influence the burning pains of open wounds, while others have produced remarkable relief by applying it to the vesicles of intercostal zona. Its action is much more lasting than that of cocain, and in all the cases published, the prolonga-tion of the anæsthesia was counted, not only by minutes, but by hours. Its average is twelve hours, but it extends sometimes to twenty-four and exceptionally to forty-eight hours (Einhorn). But this action is not exercised on the intact epithelium as is the case with cocain; placed on the tongue, orthoform does not produce the numbing sensation of the latter. The dermis must be exposed so that the powder can be brought in direct contact with the nerve terminals. Its essential indication is, therefore, the existence of a raw surface, however slight; under these conditions, orthoform produces absolute sup-pression of sensibility. It is necessary also that the contact with the wound be continuous as long as the desired effect is needed; it would appear that its slow solubility in the liquids of the human economy is the cause of the duration of the effect.

For the last six months I have employed orthoform in the maternity of the Charité Hospital in forty cases of fissure of the nipples. All the patients without exception experienced almost instant relief. I tried it in four different ways; the powder with wet dressing; the powder in the dry state; and lastly, a saturated alcoholic solution. The first mode of application was employed in 29 cases, and consisted simply in the direct application of the orthoform to the fissure and covering with a compress moistened with a solution of boric acid, with a piece of oil silk over all; the dressing was removed each time the child was put to the breast, and replaced after that function. The dry application was followed in six cases, and differed only from the former by the gauze being applied in the dry state; whilst the alcoholic dressing consisted in pouring four drops

of a saturated alcoholic solution of orthoform on the fissures, followed by a dry compress. Each time the patients experienced a slight burning sensation for a few moments, but the operation of nursing was rendered almost painless—especially when the alcoholic dressing was applied. As the effect of the orthoform lasts several hours, it is not necessary to apply it each time the breast is given. One point worthy of mention, in conclusion, is the cicatrising action of orthoform. Under its influence, I have seen the fissures heal more rapidly than with any other dressing. In the cases above mentioned, the time taken was, on the average, four days without stopping the nursing, whilst with other treatments it took from ten to twelve days, and, moreover, nursing had to be suspended.

In short, orthoform seems to me to render good service in the treatment of fissure of the nipples, no matter how extensive, and of all the preparations it is to the alcoholic solution that I would give the preference. Four drops are sufficient to bring about the desired effect in the space of from five to ten

minutes.

THE UPPER TERMINATIONS OF THE ANTERO-LATERAL AND DIRECT CEREBELLAR TRACTS (a)

By ALEXANDER BRUCE, M.D., F.R.C P.Ed., lecturer on Pathology in the Edinburgh School of Medicine, Assistant Physician to the Edinburgh Boyal Infirmary.

THE symptoms of cerebellar disease were divisible into two classes:-those ordinarily present in cerebral lesion - headache, vomiting, optic neuritis, and the like; and lo alising symptoms, such as vertigo, ataxic gait and movements of the eyes. The varia tions in the symptoms met with in cases of cerebellar tumour were due, not to differences in the nature of the lesions, but to differences in their situations. Nothnagel was one of the first to point out that disturbance of equilibration was present only in lesions of the middle lobe, not in affections of the lateral lobes. This statement, however, required qualification, since slow growing tumours of the middle lobe might remain latent, while those of the lateral lobes might produce alterations of equilibration. cortex of the middle lobe receives fibres from the comma tract, from the direct lateral cerebellar tract. and from the posterior columns of the cord afferent fibres are probably chiefly concerned in the conduction of muscular sense impressions; they do not convey the sensations of touch, pain, or temperature. None of the fibres of these tracts pass into the lateral lobes of the cerebellum, with the possible exception of a few which may gain entrance indirectly from the pons. The afferent fibres from the semicircular canals end in the nucleus of Deiter's, and this nucleus has extensive connections with various parts of the base of the brain. It consists of large cells, very like those of the anterior cornua, and gives off efferent fibres to the third and sixth nuclei on both sides, and also two descending tracts, which run in the anterior and antero-lateral columns respectively, and end in the anterior horns of grey matter. Thus there is, through Deiter's nucleus, a connection between the muscles of one side of the body and the ocular muscles of the same side, and to a slighter extent, the ocular muscles of the opposite side. The two systems of fibres above-mentioned—the afferent fibres entering the middle lobe of the cerebellum, and the afferent and efferent fibres connected with Deiter's nucleusare united by tracts running from the middle lobe to

the roof nucleus, and from the roof nucleus to the nucleus of Deiter's. In order that equilibration may be maintained, it is necessary that this chain of fibres be intact. There are also fibres running from the dentate nucleus (which is connected with the middle lobe) in the cerebral peduncle to the optic thalamus and cerebral cortex of the opposite side. The lateral lobes of the cerebellum get fibres only from the pons.

Lesions of the superior and inferior cerebellar peduncles cause falling to the side of section; division of the lateral lobes brings about a similar result, but this is because of the impossibility of dividing these latter structures without injuring the superior and inferior peduncles as well. An exactly mesial division of the middle lobe causes little disturbance of equilibration, because of the symmetrical nature of the lesion; equilibration as a whole is weakened, but Total ablation of a lateral not otherwise affected. lobe causes falling to the side of the lesion, but only because of the injury to the inferior and superior cerebellar peduncles. Slight injuries to the lateral lobe cause little or no disturbance. Tumours of the middle lobe affect equilibration by destroying the chain of afferent and efferent tracts, and do so especially if a little to one side of the middle line. Tumours of the lateral lobe remain latent until they press upon the dentate or Deiter's nucleus or restiorm body.

THE LESSONS IN GYNÆCOLOGY OF A YEAR.

By H. MACNAUGHTON-JONES, M.D., M.A.O., M.Ch, F.R.C.S.I. and E.,

President of the British Gynacological Society.

(Concluded.)

Passing on to consider the circumstances and local conditions which determine the surgeon to perform laparotomy, or posterior vaginal colliotomy in the treatment of extra uterine pregnancy, these have been most clearly laid down during the past year. The indications for drainage in the abdominal operation, and the necessity for efficacious drainage in both instances, with a large rubber tube of a T shape in the case of a vaginal operation, have been emphasised. After the paper I have referred to, by our late President, Mr. Mayo Robson, on extra-uterine pregnancy, perhaps the two most important contributions of the year to this subject have been those of Mr. John Taylor, who chose it as his subject for the Ingleby Lectures, which have appeared in full in our journal, and the papers by Professor Bouilly, with an analysis of fifty personal observations, contributed to the journal, La Gynæcologie. It is noteworthy that if we take the entire number of cases recorded by these three authorities, under all circumstances, propitious or otherwise, making a total of 110, there have been but six deaths-surely a splendid triumph for our art! Of these six deaths, it is noteworthy that three occurred where the abdomen was full of blood, the patients dying from erabolism and the consequences of collapse; a fourth died of septicæmia, the re-ult of fœtal decomposition, and two others from septic peritonitis, the consequence, apparently, of the debris of coagula, which became septic. Four of these deaths occurred in the fifty cases reported by Professor Bouilly, and two in the sixty cases recorded by Mr. Mayo Robson and Mr. John Taylor.

Doyen, following up his new method of performing abdominal hysterectomy, securing hæmostasis and the control of the broad ligaments without the aid of clamps, brought before the Surgical Congress of Berlin the use of his powerful lever forceps in vaginal hysterectomy, by means of which the cellular tunic of the arteries is united under a pressure of from 400 to 1,200 kilogrammes. This instrument, firmly closed for thirty seconds on each broad ligament, allows the operator to cut between it and the uterus, after which the forceps

⁽a) Abstract of paper read before the Edinburgh Medico-Churigical Society, January 18th, 1899.

can be removed without any risk of hæmorrhage. The fundus of the uterus being drawn down, the attachments of the adnexa and the pedicles of the ovaries are treated in the same manner, only a few fine ligatures being used to check the venous hæmorrhage. Doyen states that in a great number of laparotomies, and sixty vaginal hysterectomies, he has used this instrument, and has never had a case of secondary hæmorrhage. By the kindness of Dr. Doyen I show you the appliance.

Such, gentlemen, are a few of the lines on which advance in our department has progressed during the past year. They are but a small proportion of the suggestions and successes recorded by a legion of distinguished

gynæcologists working in all countries.

THE MEDICAL PRESS.

May I now state how I have personally been influenced by my own experience during the same period. This may well include the impressions made upon me by a month's visit to the Klinik of Professor Schauta in the Krankenhaus in Vienna, and to some private operations by him at the magnificent and thoroughly equipped sanatorium of Dr. Löwe.

First, I may venture a few remarks on the preparation of the patient, and some aseptic details generally. I may premise that I am more than ever convinced of the absolute need for the strictest observation of all the minute details of aseptic surgery. This term, of course, embraces such antiseptic aids as are essential and indispensable in the carrying out of asepsis. I have grown to be more searching in my general precautions, more exacting in the stringent regulations I impose on all who assist me in an operation. I have realised that perfection in the methods can only be obtained by the closest criticism of one's own personal precautionary measures, and the application of the same stringent rules to others. Allow me to cite a few common sources of danger, Final preparation of the arms and hands before the ordinary wearing apparel is covered by a clean overall: incomplete disinfection of the arms well above the elbows; the presence of finger nails; the short time spent over the sterilisation of the patient's abdomen, and particularly the umbilical depression; the preparation of the vagina. Let me, in consequence of a recent discussion at this Society, make a few observations on this simple matter. The patient is brought into the usual hysterectomy position, well to the edge of the table. The hair of the entire genitals has been previously shaved off. The abdomen and the flexures of the groins have been sterilised; the fingers with some sponge material well soaked, are now introduced into the vaginal canal which is subjected to a good lather, and, the perinæum being well depressed, this process is repeated several times, while the nurse, standing at the side, keeps up a stream of sterilised water from a douche and pipette on the parts from time to time. Finally, the entire vagina is subjected to a douche of 1 in 3,000 of mercuric perchloride. It is important to secure the mercuric perchloride. It is important to secure the thorough sterilisation of the external parts before the vagina is thus attacked. For sponging and compression with sterilised gauze and tampons, I have abandoned the use of any holder save an extremely light and long clamp forceps, which can be rapidly opened and closed on the forceps, which can be rapidly opened and closed on the tampons, and these latter, with the sponges, I have drawn out at the time and cut in the manner you see from tin boxes similar to those used for hairdressers' wool, according as I require them, in three sizes. These boxes are thoroughly disinfected before operation, and the sterilised bandages, unfolded, are then placed in them. Sterilised iodoform gauze, unrolled straight from the bandage, for tamponning the vagina (a) is similarly used. It may appear unnecessary to even hint at a caution which everyone is supposed to take with regard to catheterisation of the bladder after operation, when such a step is necessary. Still, it is remarkable how much laxity appertains in this matter. Sterilised glass catheters should be kept in perchloride solution, and two be used for each patient, one to be sterilised and kept ready to replace the other when required Many a case of cystitis would be avoided if this precaution were taken, and early and gentle washing out of the bladder

(a) All such sterilised bandages can now be had in hermetically sealed boxes ready for use.

practised when the condition of the urine indicated this

step
We are constantly hearing of the importance of rapidity of operation, both abdominal and vaginal. Personally, if there be one thing more than another that I am convinced of, it is this, that it is perfection of detail, and not rapidity of execution, that all and especially young operators, should aim at. Doubtless there are parts of every operation which should be done as expeditiously as is possible, consistently with accuracy and neatness, and every appliance which helps us in this direction is to be welcomed. As much in this respect possibly depends upon the assistant who supervises the instruments as on the operator, but I am certain that in the cautious protection of bowel throughout an operation, in the perfect adaptation of peritoneal surfacer and edges, in the complete and certain stasis by ligature of every bleeding vessel and point, no matter how fine, in the cleanliness of exposed parts and surfaces before final closure of the wound, the safety and ultimate perfect recovery of the woman depend, rather than upon rapidity of manipulation on the part of an operator.

I have recently operated under the following condi-tions, which I shall but briefly enumerate, as I hope to refer to the cases on a future occasion. A woman, æt. 30, was confined five weeks before I saw her in consulta-The delivery was followed within forty-eight hours by an elevation of temperature, and it was noticed that the abdomen was swollen, and appeared to contain fluid. The temperature remained erratic, varying in a range between 102 deg. and 105 deg. until saw her, when she was undoubtedly very ill confirmed the view that we had to deal with a fairly large overian cyst which had probably suppurated, and that immediate operation was called for. Accordingly, within forty-eight hours I operated Dr. Allen, of Stanmore, assisting me. The cyst wall was greatly thickened, closely adherent to the entire parietal peritoneum, which had literally to be peeled off at both sides, after the cyst had been tapped and syphoned of Most difficult was the approach to a very broad pedicle, adhesions having been formed between the rectum at the left side, and the sac and an elongated and greatly enlarged Fallopian tube. The pedicle, however, was secured in three portions, and then came the most difficult part of the operation. The sac was firmly adherent posteriorly all over its surface to the bowel, the colon and meso-colon were plastered to it above, with the omentum, requiring the greatest care in separation, and considerable difficulty in the arrest of bleeding. However, finally the sac was removed in its entirety, all bleeding was arrested, the abdominal and pelvic cavities were left perfectly clean, and an operation, which lasted two hours and a half, was completed. The anæsthetic was ether; the patient suffered from no shock, and has made a good recovery. The bowel was protected all through as carefully as possible by small napkins of flannelette wrung out of warm sterilised water.

Quite recently I had an abdominal hysterectomy for a medium-sized fibroms, in which the left broad ligament was involved within the growth. The patient was exceptionally fat, and though the delivery of the tumour was rapid, I met with extreme difficulty in carrying out hemostasis, which was, however, in the end most completely secured, though the operation occupied a period of over two hours. There was no shock, and there was a rapid recovery. I believe that if there be shock, directly resulting from an operation conducted under profound anæsthesia, it is much more likely to follow upon rough manipulation, injury to vital parts, unnecessary dragging and possible laceration of sensitive structures, than upon a necessarily increased dura-tion of the operation. More recently still I operated by vaginal hysterectomy on a case of old and extreme procidentia, in which the bladder contained in the tumour had to be freed from firm adhesions, which reached to within half an inch of the margin of the os uteri. There was a large retroverted uterus. The operation was very prolonged, and there was subsequently shock; but here haste would have been disastrous—in all probability involving me in serious trouble with the bladder

or ureters.

THE MEDICAL PRESS.

As to the material which I use for ligatures and sutures, I have had the most complete satisfaction for gut prepared after the method adopted by Martin, of Berlin. Silk I now sterilise by Howard Kelly's method. This gut is perfectly pliable, is strong enough for any purpose, and has no liability to slip. I adhere with perfect confidence to the triple suture for closure of the abdominal wound, fine silk for the peritoneum. stronger for the well-adapted muscle and fascia, and silk-worm gut for the skin.

Hitherto I have had but one solitary experience of ventral hernia. This occurred in a patient mentally affected and who twice did all in her power to force open the abdominal wound, both before and after the sutures were removed. When I last saw her the protrusion was quite cured, after a dissection out of the entire cicatrix

and readjustment of the layers.

If I presume to say what my personal feeling is with regard to a few disputed points connected with operative gynecology, I do so from no egotistical desire to parade my own views. I may alter my present convictions, but those which I now feel are the results not only of my own experience, but the work which I have seen done by such advocates of different methods as Doyen, Hartmann, the Landaus, Olshausen and Winter, Martin, Schauta. and others. In all cases where there is doubt as to the feasibility of removal of the adnexa through adhesions, tumours, or collections of pus, by the vagina, laparotomy is the safest and most expeditious mode of operation. The same rule applies to myomata of a certain size, and to myoma complicating cancer of the uterus. Laparotomy still remains the safest and most classical method of dealing with ovarian cystoma. In small adnexal tumours, dependent upon their situation, anterior or posterior colpotomy is the most direct, as well as the safest means of operative diagnosis. For all cases of small adnexal tumours, vaginal collictomy is the route, which, both anatomically and clinically, should be followed, and the same remark applies to movable and small myomata and ovarian dermoids. In certain cases in which unexpected or insuperable obstacles are met with in the vaginal method, resort should be had to the combined operation. Operation by ligature is the most satisfactory, as it is the safest method in vaginal hysterectomy. While intra-peritoneal myo-hysterectomy, leaving the cervical stump, and carefully uniting the severed peritoneum, is in certain cases an admirable operation, it is not as complete nor as classical a step as total hysterectomy. This latter operation should be completed by careful adaptation of the peritoneal flaps, covering of the ovaries with the peritoneum, and shutting out of the vaginal canal by suturing the peritoneum anteriorly and posteriorly to the cut vaginal edges, followed by their adaptation. Only in exceptional cases, such as those complicated by adnexal tumours with fluid contents, need vaginal drainage be resorted to. The classical operation for a large double pyo-salpinx is laparotomy, with ablation of the diseased sacs, total hysterectomy, and completed as I have just said, by

A few words descriptive of the work I saw in Professor Schauta's Klinik this year in Vienna may interest the Fellows. Besides various minor operations, plastic and other, there were twelve vaginal hystero-ophorectomies, one for myoma with adnexal tumour, one for double pyosalpinx, six for various adnexal tumours, one for tubal gestation and hæmatocele, two for malignant conditions of the endometrium, one for chronic metritis with dermoid tumour of the ovary; three operations for abdominal total hysterectomy, two for simple myoma, and one for myoma and malignant disease; two operations of abdominal salpingo-opphorectomy, both for tubal gestation, with rupture and hæmatocele; two ovariotomies, one abdominal, the other vaginal, both for cystoma, and one abandoned laparotomy for tumour of the adnexa and

peritoneal adhesions.

I followed for several days the course of all these wees. Without exception they all did well, and I have since heard from Dr. Schmit the final result, which has been recovery in every instance. One of the cases of abdominal total hysterectomy was interesting, as occur-

ring in a patient, aged 73, in whom the myoma was complicated with malignant disease of the uterus. In another, bi-lateral pyo-salpinx occurred as a complica-tion of hæmatocele, the consequence of an extrain characteristic fashion over the interior of the sac In a third case, an extra-uterine feetation had been operated on two years previously, and a portion of the adnexa had been left. The operation was most difficult, in consequence of firm and extensive It will be noticed that of twenty major adhesions. operations, thirteen were performed per vaginam, and Professor Schauta is emphatic as to his preference for this route over the abdominal one whenever it is feasible to adopt it. It is more difficult, he says, but it is the most natural and the safest for the patient. I saw him remove a fair-sized ovarian cyst by the vagina, performing anterior colpotomy, tapping the cyst, withdrawing the sac, subsequently stitching the parietal peritoneum to the uterine peritoneum, and the vaginal wall to the One case of large bi-lateral pyo-salpinx was uterus. operated on by posterior colpotomy, the coliotomy being rendered extremely difficult through the adhesions. The time occupied in performing the vaginal hysterectomy varied. One I saw completed in about twenty minutes, while the more difficult ones occupied over an hour, and on one or two occasions an hour and a half, and even more. The anæsthetic employed is a mixture of chloroform 1 pt., ether petrolei 1 pt., ether sulphine 2 pts. Professor Schauta uses no clamps. Having made the usual incision, he opens the anterior peritoneum, ligatures the uterine vessels at either side, and frees the cervix completely, sometimes dividing it, or occasionally removing it altogether. The adnexal vessels are next ligatured at one side, and if the adnex be removed they are brought through the posterior opening. This is repeated at the other side. Occasionally, if there be difficulty, the fundus is divided so as to permit of either half being grasped, thus allowing of greater feeedom of manipulation, as well as increase of room. Silk is the material used altogether, both for ligature and for suture. I should mention that as soon as the peritoneum has been opened, its edge is carefully stitched to the vaginal wall in front. Subsequently, the posterior section is treated in a similar manner. A roll of sterilised icdoform gauze of some twenty to twenty four inches is passed up through the peritoneal opening, and tied with a string to distinguish it before it is severed, and then the vagina is loosely packed with more iodoform gauze. The vaginal sutures are left long, and are removed in about three weeks. This is very easily done. The internal strip of gauze is not removed for eight or ten days. Only on one occasion, after any of these vaginal operations, did I see a clamp remain for security's sake, in a difficult case of hæmostasis. Abdominal hysterectomy is not performed by Doyen's method. The tumour is delivered, severed and freed by ligature and section at either side from above down. The vagina is then opened, and the cervix is freed; most accurate adaptation of all peritoneal edges is obtained, the cut and exposed surfaces of the adnexa are covered carefully, iodoform is passed from above down into the vagina, and the peritoneum, with the vaginal opening is closed.

If there be any associated purulent condition of the adnexa an iodoform drain is pushed through into the vagina as usual. Speaking generally of his operations, I may say that they are performed under the strictest aseptic precautions; that there is no evidence of haste, but from first to last the most cautious and deliberate manipulation to secure the most complete hæmostasis and perfect cleanliness of all the parts exposed during operation. The toilette of the abdomen is secured by triple suture, and the patient is laid on a portable couch, on which is spread ready the waterproof sheeting, an outward swathe and an inner one of domette to make the tail bandage. Thus she is dressed with the least disturbance before being rolled into the ward. I have here a few appliances of Professor Schauta's which are inter esting. His needle-holder for vaginal hysterectomy, curved, as you see, in the handle, which makes it more convenient than the straight instrument for carrying the needle laterally; and his ligature tightener, which enables the surgeon to tighten effectually a ligature placed on a deep-seated or inaccessible vessel. As a rule he uses Deschamp's needles for carrying the lateral ligatures, but for the control of special vessels and sutures he employs this holder.

I would wish, had there been time at my disposal, to say a word of the arrangements at the magnificent sanstoria of Löwe and Fürch. In the former, especially, the suites of operating theatres, with their adjacent rooms for anesthetisation and washing purposes, as well as dressing-rooms for the surgeons and assistants, make one envious of the splendid facilities which a Vienna surgeon has for operating in private. No conceivable want is here left unfulfilled, and under an able directorate and staff, the patients are secured the very best attention.

Gentlemen, may I conclude this very impertect summary of some of the lessons learned during the past year, and the reflections they have given rise to, by the expression of the hope that during our debates and discussions throughout the coming Session, the tone and character of our proceedings may be stamped by the recognition of our high aims and aspirations. A Society, like an individual, to be accounted worthy must be incited by ambition, and that is a poor ambition which site down to follow afar off the lead of others who struggle in the same direction. Gynæcology, doubtless, is one of the younger handmaidens of medicine, yet so rapid has been her growth that the has outstripped in the importance of her discoveries and her art many of her older sisters in the race of advance. Let it be our justifiable boast that in our Transactions will be found work that entitles us to a foremost place among the many medical and scientific societies labouring ever unselfishly in the cause of progress and humanity.

Transactions of Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD JANUARY 18TH, 1899.

Dr. P. A. Young, Vice-President, in the Chair.

EXHIBITION OF PATIENTS.

Mr. Greig showed a case of congenital symmetrical perforation of both parietal bones. Two openings measuring 2 by 3½ cm. could be felt at the posterior superior angles of the bones, just in front of the lambdoidal suture. Firm pressure on these caused vertigo and flashes of light before the eyes. Otherwise the patient suffered no inconvenience; he had served in the army as a driver of artillery, and the condition had in no way interfered with the performance of his duties. Five such cases had been previously recorded, but the lesion had never before been discover d during life.

Mr. CAIRD and Mr. Guy showed a case of extensive destruction of the nose and palate due to tertiary

syphilis.

EXHIBITION OF SPECIMENS.

Dr. HARVEY LITTLEJOHN showed the following specimens from medico legal cases:—(1) Three hearts, two of which were hypertrophied; one of these (weighing 49 ozs.) was as large as any recorded. The third preparation was an example of spontaneous rupture of the musculi papillares and inner wall of the left ventricle. (2) A specimen of effusion of blood on the surface of the brain.

Dr. ALEXANDER BRUCE read a paper on the

UPPER TERMINATIONS OF THE ASCENDING ANTERO-LATERAL AND DIRECT CEREBELLAR TRACTS.

An abstract of which will be found in another column. Dr. Shennan and Mr. Miles read a paper on

A CASE OF APHASIA.

The patient had suffered from left-sided otorrhea and deafness for three months. For three days before admission he had had acute pain in the ear and left side of the head. As the symptoms pointed to mastoid disease the antrum was drained, but signs of cerebral abscess developed. Mr. Miles trephined over the temporo-

sphenoidal lobe, and found an abscess at its lower part. After the operation the patient improved greatly, was noticed to be paraphasic; he cons antly misplaced words, especially substantives. There were neither word-deafness nor word-blindness; he could read, write, and copy well. He progressed satisfactorily for a fortnight, and then became stuporose on account of the abscess not draining properly. After some pus was evacuated he again improved, but first facial paralysis, and then a hernia cerebri developed. Eventually he died two months after admission. He remained paraphasic throughout, the symptom being practically limited to the perpetual misuse of substantives. The diagnosis made was that an abscess was cutting off the fibres running between the auditory centre and Broca's convolution, and this was confirmed post-mortem.

Dr. WM. ELDER, in discussing the case, expressed the opinion that the ordinary speech centres were capable of further subdivision. From cases he had seen he believed that the memories of nouns were stored in an "annexe" of the word-hearing centre, and that this annexe was connected with the visual centre in the occipital lobe. Similarly, he thought that there was a special centre for the memory of verbs, and that this was connected with

the motor areas.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY. MBETINGS HELD DECEMBER 8TH AND 22ND, 1898.

The President, Dr. ALFRED ROBINSON (Rotherham), in the Chair.

DR. ARTHUR HALL showed cases of seborrhœic eczema. Addison's disease, and hydroa of pregnancy photographs.

Mr. ARCHIBALD CUFF demonstrated peculiarities of gaits and other abnormalities in a ricketty dwarf.

Dr. Sinclair White exhibited and made remarks on Dr. Sinclair White exhibited and made remarks on (1) a case of movable hydronephrotic kidney cured by nephropexy. (2) gall-stones-cholecystotomy with choledochotomy, (3) large cartilage removed from the knee-joint, (4) traumatic aneurysm of brachial artery treated by the method of Antyllus, (5) spinal meningocele treated by excision of the sac, (6) cancerous uterus removed by colpo-hysterectomy.

Mr. RUPERT WATERHOUSE showed a brain with old cyst and recent blood clot causing right and left hemiplegia respectively at an interval of a year. Mr. Waterhouse also related a case of skin eruption, following the administration of a simple enema.

Dr. Adams showed a specimen of malignant growth of esophagus with secondary growths on liver, and gave

clinical and other particulars of the case.

Dr. Bardswill read a paper on "Supra-renal extract

as a local anæsthetic.' Mr. WILFRED STOKES read a paper on "Synovitis associated with interstitial keratitis.

Mr. Priestly showed a case of sporadic cretinism with photographs before and after treatment by thyroid extract.

Mr. Tull introduced a young man, from whose retina of right eye a piece of metal had been extracted with the electro-magnet. The fragment had been observed with the ophthalmoscope in the retina, and the result after removal was excellent.

Dr. 8 mith on a case of

PROGRESSIVE MUSCULAR ATROPHY COMMENCING IN THE LEGS.

Mrs. C., et., 53, married, one child (stillborn), consulted me in May, complaining of weakness in legs. Illness commenced five years ago, when she noticed first a difficulty in dorsiflexing the feet, particularly on going upstairs. She also states that previous to this she had had a good deal of mental worry in connection with her family affairs. Examination shows both feet in the position of "drop foot," and considerable wasting of the muscles in front of the legs, the thigh muscles, and the glutei. Dorsiflexis of toes and feet is completely lost, and movements at knees and hips are feeble. Patient cannot walk without assistance, e.g., by support-

Digitized by Google

ing herself by a table or chair. She cannot rise from a chair without assisting herself with her arms. The right side is worse than the left. The upper extremities are unaffected. Sensation is unaffected, although the limbs are cold and often livid. Bladder and rectum are normal. The muscles have not been tested for the R.D. Fibrillary tremors have not been observed. Both knee jerks are absent. From the fact that this patient first noticed a difficulty in dorsiflexing the feet, the disease probably started in the peronei and anterior tibial muscles. Treatment has been strychnine, iron and arsenic, and friction of the muscles She has also been using a Faradic machine. The patient fancies she has slightly improved.

Mr. R. FAVELL related a case of pan-hysterectomy which he had performed for myoma of uterus. The woman was aged 42, and during the last few months the periods had been very profuse. Three months before she was operated upon the hæmorrhage was so great that she thought she would have died. The uterus when removed weighed six and a half pounds. The myoma was found to be undergoing myxomatous degeneration, and a small fibroid in the wall of the uterus was under-going calcification. The patient had made a good

recovery.

Also, a multilocular ovarian tumour removed from a young woman. The tumour was disease of the left ovary, and to this the fimbriated end of the Fallopian tube of the opposite side had become firmly adherent. Also, a parovarian cyst removed from a woman, æt. 24.

Dr. ARTHUR HALL showed a case of

HERPES ZOSTER

of the left side of the thorax in a little boy who had been undergoing a prolonged course of arsenic for enlarged glands. After the first appearance of the eruption, owing to a misunderstanding on the part of the parents the medicine had not been omitted, with the result that in spite of the rash being dressed with sedative ointment and well protected, it had gone on to severe serpiginous ulceration. As soon as the arsenic was left off the ulcers began to heal rapidly.

Dr. Hall also showed photographs of double primary

syphilitic sores of the hand in a midwife. The two sores appeared the same day and ran an exactly similar course. The secondary symptoms appeared a few weeks later.

Dr. Hall also related a case of papulo erythematous rash due to boracic acid. The patient had been taking half a drachm per day for about two weeks when it appeared. The irritation at night was considerable, and remained unrelieved by various sedatives, lotions, &c. The boracic acid was then left off, and in the course of a few days the rash disappeared altogether. On resuming the drug, an irritable scarlatiniform rash appeared within forty-eight hours, which again subsided on the drug being left off. The patient was suffering from old stricture with cystitis. There were no other symptoms of boracic acid poisoning.

Mr. Makeig Jones showed a boy, et. 19, with congenital hypertrophy of the three middle toes of left foot -a condition known by the name of giant toes; also

A man, æt. 55, with amyotrophic paralysis of right arm and leg, coming on three weeks after slight injury to the right elbow and ankle joints fourteen months ago. The condition was now improving, but there had lately supervened contracture of the calf muscles. He had shown several similar cases at the Society and described them as a progressive muscular atrophy due to atrophic changes at the motor nerve root. He also suggested that many of the cases of ruptured nerves during reduction of shoulder dislocations were really similar trophic lesions.

Dr. Robertson read a paper on

INFANT-FEEDING AND EPIDEMIC DIARRHOLA,

in which he pointed out that there was ample evidence to show that epidemic diarrhoea was mainly due to ignorance and carelessness in the feeding of young children, while much might be done in the way of limiting the disease by improving the sanitary surroundings of the dwelling and enabling a clean milk to be pro-Yet the real point to be attended to was the curable. greater attention to cleanliness in feeding and rearing of infants. Such an object was extremely difficult to attain, but there was reason to believe that much could be done by the general distribution of leaflets on the subject to persons registering the birth of children. Such leaflets if well drawn up formed the basis on which the work of lady visitors rested and in time became the accepted model for the particular district.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, Janua y 22nd., 1899.

PROPHYLACTIC MEASURES FOR THE PLAGUE.

M. Proust read a paper at the last meeting of the Académie de Médecine on the prophylactic measures to be taken against the invasion of the Indian plague into Europe, in which he said that the plague continued to ravage with intensity India, and more particularly in Bombay; it had also made its appearance in some parts of China and in Madagascar. It was of the utmost importance that the different measures already advised against the importation of the plague into Europe should be perfected and completed. Sanitary measures should be taken on the land frontiers and on the sea.

The attention of Europe should be drawn to the Persian Gulf, where no protection existed in spite of the neighbourhood of the contaminated districts, for if the plague traversed the Gulf Europe would be soon threatened. The prescriptions of the sanitary conferences were not executed sufficiently. The institution of the medical visit at Suez would be effectual if properly carried out, but false declarations on the part of the dectors and of the captains of vessels have been known to have been made. When a plague epidemic broke out on board ship, the patients should be brought to shore as quickly as possible and placed in the sanitary station, while the rats, which were powerful agents of contamination, should be utterly destroyed, and the vessel completely disinfected.

To accomplish these different desiderata, it is not necessary to call a new conference, as all the important prescriptions concerning the prophylaxis of plague and cholera were to be found in the conventions of Venice, Dresden, and Paris. What was necessary, however, was that the Governments should combine to execute seriously what the conferences had decided.

THE RONTGEN RAYS.

At the Sociéte de Dermatologie, M. Bulzer presented a patient, who for the last year was submitted every day in a museum to the action of the X-rays. The result was cutaneous lesions on different parts of the body. The right hand and forearm were the seat of red and hard ædema; the skin of a violet tint, cracked and covered with a yellowish crust. The nails had fallen, but grew again thick and clubbed, The neck and right side of the face were also the seat of lesions, but in a less marked manner, while complete alopecia was found over the parietal region of the same side, and the beard and moustache had also disappeared.

M. Barthelemy said that alopecia was alway observed following repeated expositions to the Rontgen rays when the tube was not held at a sufficient distance. He had remarked that individuals whose skin was naturally moist were particularly subject to these accidents. M. Brocq said a patient came under his notice suffering from acnea with hypertricosis She had come from Vienna, where she was treated by the X-rays seventeen

consecutive times, being assured that a cure was certain. Although the acnea had rather increased under the treatment the hairs were dead and seemed ready to fall off. He asked his colleagues if they thought that they would not grow again. He was replied to by M. Barthelemy, who said that in the seven or eight cases of alopecia he had observed, he always found that the hair began to grow again after two months.

INJECTIONS OF CALOMEL AND ORTHOFORM.

M. Daulos presented a patient who suffered from sclerogummatous glossitis of syphilitic origin. Some time ago his tongue had increased so much in volume and had become so painful that his life was in danger. Every kind of specific treatment had been tried without result, and injections of calomel were advised, but the patient dreaded the pain produced by the treatment. In order to satisfy him the speaker thought of trying orthoform with the calo mel, and employed the following formula:—

Calomel, j gr.; Orthoform, ii gr.; Vaseline oil, xx drops.

The therapeutic results were excellent, and, what was worthy of remark, the patient suffered no pain, only a little soreness on the fourth day, the period when the injections of calomel provoke generally intolerable suffering. He had thus practised five injections with the same success. He thought that as orthoform was without danger his formula was worthy of further trial.

TINCTURE OF IODINE

Prof. Grosch strongly recommends the administration of tincture of iodine in the treatment in all kinds of gastro-intestinal affections, and especially in the diarrhea of typhoid fever both in children and in adults. In children suffering from typhoid fever he gave four drops of the tincture overy eight hours in sugared water. The temperature fell rapidly and the diarrhea disappeared in four days. In adults he administered six drops three or four times a day. Of the forty cases thus treated none succumbed, and the favourable symptoms appeared at the outset of the treatment.

In acute gastro-intestinal affections of an infectious nature the results were signally favourable in the cases where the fever ran high, with vomiting and fetid diarrhœa. In infants the author gave one drop of the tincture of iodine three times a day.

LUNATICS AND HABITUAL DRUNKARDS.

A Bill has just been introduced in the Senate for the establishment by the Government of institutions devoted exclusively to the incarceration and treatment of lunatics, habitual inebriates, and dangerous patients. grounds on which incarceration may be decreed by the Courts are stated, and the measure compels the placing in the asylums of criminals acquitted at Courts of Assizes on the ground of irresponsibility. It further provides that "Incarceration in a Special State Asylum shall be ordered when the lunatic has exhibited homicidal intents or a bent towards disgraceful assaults or arson, or when his depraved morals or perverse habits render him dangerous to other people." It is high time that such a law should be passed, for it is intolerable that lunatics and inebriates, forced despite themselves into the commission of crime, should be allowed to run about the streets, leaving death and dishonour in their track.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, January 20th, 1899.

ADULTERATION.

THE adulteration of articles of food appears to bepractised on a large scale in certain parts of Germany. Some statistics recently to hand from the municipal laboratory of Dresden show that out of 143 samples of butter analysed by the authorities, no less than 33 were condemned by reason of their admixture with foreign fats, the presence of an excess of salt, or by reason of advanced decomposition. This kind of adulteration, says the municipal chemist, is carried on in "a most unblushing fashion." Next to butter, honey seems to be a favourite object of fraudulent adulteration. Dresden, as elsewhere, milk is still largely adulterated, in spite of the severe penalties directed against the practice. As might be expected in a country wheresausages form a staple article of daily consumption, adulteration in various forms is rampant. The principal adulterant is potato flour, enabling the merchant tomake use of dry or poor quality meat. To mix it with meat the addition of a considerable quantity of water is necessary, rendering sausages thus compounded peculiarly liable to undergo decomposition. The proportionof the adulterant varied between 1 and 13 per cent It would seem, indeed, that in respect of fraudulent adulteration the Germans "have accomplished really remarkable progress."

At the Medical Society Hr. A. Baginsky read a paper on

Pericarditis In Childhood.

Pericarditis in common with a number of other diseases was formerly considered to be infrequent in childhood. Recent and more thorough observation had, however, taught to the contrary. Data varied and it was difficult to give a correct estimate of the frequency of the disease. He had made the observation that pericarditis was highly dangerous for childhood. He had observed sixtyfour or sixty five cases of the disease in children under the fourteenth year in the K. K. Friedrich Hospital. Primary or accompanying diseases were twenty-four times rheumatic polyarthritis, eleven times tuberculosis, eleven times pleuro-pneumonia, seven times erysipelas and phlegmon, six times purulent pleuritis, five times severe diarrhœa, six times measles or pneumonia, twice scarlatina, twice meningitis, twice otitis, twice diphtheria, &c. In some cases decided septic processes were in play. Rheumatism was more frequent in children than was believed. During the period under notice he had seen 145 cases (with or without chorea). exudation was either serous, fibrinous, hæmorrhagic, or purulent. There might be or might not be obliteration of the pericardium in the fibrinous cases. The serous form was observed in nine boys and seven girls. The symptoms were severe, especially in the arthritic cases. The diagnosis was very difficult. Dislocation of the heart with change of position were very small. The most important sign was the pericardial murmur. Purulent exudation was still more difficult to diagnose, a consideration of the accompanying symptoms was necessary. The speaker found pus in connection with erysipelas, grave angina, caries of the ribs, diffuse peritonitis, broncho-pneumonia, gastroenteritis, furunculosis, phelg-

mon of the neck, and double empyæma. The grave general symptom here predominated. He had seen septic diseases at the earlier ages (once in a child ten days old, twice at two years). Sudden rises of temperature pointed to the presence of a malignant process. Bacteriologically he had found bacterium coli, streptoc. staphyloc. pyocyaureus. Tuberculous pericarditis was much more rare, but when it did occur very malignant. He had seen eleven cases. The most frequent form was the polyarthritic. In childhood the early participation of the heart was the rule (according to Broadbent it was constant). Not infrequently later relapses took place, and these were often fatal. Children who had suffered from these diseases in childhood were in danger of recurrence in adult age, and often died in them. Salicylic acid often failed in these cases, inf digitalis, with large doses of diuretin (4 to 5 grm. daily) was better, especially if symptoms of stasis came on (dropsy, with tendency to suffocation). In place of digitalis strophanthus was

Hr. Leop. Casper gave a further report on

CATHETERISATION OF THE URETERS, comprising three interesting cases he had met with during the past four years. In the first case, after 36 hours' anuria, the ureteral catheter was passed. Five ctm. above the bladder opening the instrument came on an obstruction that could not be removed. Oil was then injected, and less came away than was injected. The patient was then put to bed. In 20 minutes' time 200 grms. of fluid were removed, and the following morning six litres. The second case was that of a young woman, with enlarged pelvis of the kidney and purulent urine. The kidney pelvis was washed out 13 or 14 times at intervals of six days, with silver nitrate solution. The kidney tumour gradually disappeared, and all the other symptoms subsided. The third case was one of pyelonephrosis in a man of 24. The pelvis was washed out, but a rigor and high temperature followed. After nine washings out the urine was thicker than ever, and it was decided that the kidney was tuberculous. At this point, however, all changed: the urine became c'ear, the kidney tumour subsided, and at present the man was well and fit for work

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 21st. 1899. VIBRATION THEBAPY.

We have again to discover the genius who devised the vibratory theory of treatment which is now set forth in the Clinical Review, by Herschell, who strongly advocates this method of treatment in obstinate constipation, and who seemingly lays claim to it being his own invention. No one can doubt the original description of his apparatus as peculiar to himself when an Austrian is told that it resembles the "stocke" or baton, carried by a "constable in England."

I often wonder how many Austrians will profit by this resemblance! This baton, or "stocke," is connected and kept in motion by an electric motor when applied to the bowel.

The novel "Vibrateur" is discovered to be nothing more than a modification of the Abbé Saint-Pierre method, who practised this form of treatment one hundred years ago for migraine and gastralgia, with a "vibratory instrument." At a later period Zander revived the treatment, and more recently Charcot devised a "vibrating chair" for a similar purpose. Whatever the English constable's baton may accomplish, it is evidently not a novelty in principle.

THROMBUS IN TRANSVERSE SINUS.

At the Gesel'schaft der Aerzte, Biel showed a man whom he had operated on for "Thrombophlebitis sinus transversi ex otitide." The sinus was reached by an opening made through the mastoid portion of the temporal bone, and in order to enlarge the opening the jugular vein was ligatured. The wound healed and recovery followed. The first surgeon who performed this operation was Zaufal, who met with considerable success.

KERATOMALACIA.

Elschnig showed preparations and photogrammes to the Society from a case of keratomalacia. This disease was first fully described by Graefe in 1866 as a morbid condition frequently occurring in infantile encephalitis-It has recently been established by different authorities as of bacterial origin.

The preparations were taken from the cornea of a woman, æt. 51, who was brought to hospital complaining of icterus and enlargement of the liver. On the cornea of the right eye was a large cicatrix, while the left had a deep circular ulcer; in both conjunctive the xerosis was promiently present.

She died shortly after admission The post mortenr revealed a carcinomatous condition of the ductus choledochus. A closer examination of the cornea disclosed long bands across its surface containing large groups of cocci. The xerosis had an undoubted effect on the keratomalacia, as it prevented the complete closing of the lids, and thus the proper moistening of the cornea, which would hasten the retrograde process. The effects of the icterus was to produce well marked xanthelasma of the lids.

In the discussion that followed, Prof. Kaposi thought the morbid process was inverted in this case, that the icterus was the consequence of xanthelasma and not the canse of icterus, as the xanthelasma process finally attacks the liver.

Prof. Paltauf remarked that xanthelasma not infrequently accompanied cirrhosis of the liver which might have been the case in the present instance.

ECTOPIA VESICÆ.

Frank brought forward a young lad on whom he had operated for ectopia of the bladder. He made an opening through the wall of the bowel at the sigmoid flexure into which he attached the ureters where they have united and healed.

The recovery was a perfect success; nothing but a slight oozing was observed for a short time after the operation, which soon disappeared.

The boy can now hold his urine in the rectum for three or four hours at a time. This interval he hopes will yet be further extended, as nature becomes accustomed to the abnormal habit.

SIR WILLIAM BROADBENT, Bart., had conferred upon him, on Monday last, the honorary degree of LL.D. of the University of St. Andrews.

The Operating Theatres.

SEAMEN'S BRANCH HOSTITAL, ROYAL ALBERT DOCKS.

OPERATION FOR FRACTURED PATELLA.- Mr. WILLIAM TURNER operated on a man, set. 43, who had been admitted the same morning for a fractured patella caused by a fall whilst pulling a truck. The right patella was fractured transversely a little below the middle, the separation between the fragments was about the breadth of two fingers; there was no swelling of the joint nor any external marks of violence. The limb was shaved and cleansed with soda and turpentine and purified with 1 in 20 carbolic lotion and 1 in 2,000 perchloride solution. The operation was performed eight hours after the patient's admission. The limb having been again purified on the operating table a curved incision about four inches long was made on the outside of the ratella, and the joint opened, continuous irrigation of 1 in 5,000 perchloride solution being kept up. The bone was found to be fractured transversely about its middle; covering each fractured surface was a strip of fascia like a curtain. A silver wire was next passed on each side of the middle line by means of a grooved drill, and in this manner the parts of the patella were brought into good apposition, the wires being passed so as not to injure the articular cartilage and the knots carefully imbedded in the periosteum, care also being taken to turn upwards and downwards respectively the curtain-like pieces of fascia into which also incisions were made over the bone, so as to allow the wire to rest next to the osseous surface, the fascia being finally sewn over the wire and the edges of the bone. The joint was made as dry as possible, and the skin wound sewn up A back splint was applied, and the patient taken back to bed, where the whole limb would be elevated nearly at right angles to the trunk by means of a sling and an Mr. Turner said the man had inclined plane. been admitted immediately after the accident. and this allowed rest and ice to be applied at once, thus diminishing the amount of extravasation into the joint. He had performed the operation on the same day as the accident, which is not recommended by all surgeons, but in his opinion, by this early operation the damage to the tissue by the extravasated blood is diminished, the chances of traumatic synovitis are lessened, and there is a distinct gain to the patient of one week in the convalescence. Another point also in favour of early operation, he remarked, was that the quadriceps extensor had not time to waste to any great extent Mr. Turner said he always advocated the open method in cases of displacement of the fragments, particularly on account of the curtain of fibrous tissue which is invariably found between the broken surfaces. He prefers the external incision to any of the others usually employed as the scar is not knelt upon afterwards, the cicatrix does not stretch with early movement of the joint, and it is far removed from the silver wire. He drew attention to the grooved drill he had employed, which had the advantage of simplifying the passage of the wires, these being passed down the groove of the instrument without removing it. He pointed out that the man after being transported to bed would have the whole limb elevated nearly to a right angle with the body by means of a sling to the head of the bed.

the back splint resting on an inclined plane; position, he said, was originally recommended by Lord Lister, it had the particular advantage of lessening the amount of effusion into the joint. He pointed out that in the dressing of the case on the operating table it is important to bandage on the dressing before applying the splint, so that when the splint is removed the dressing remains intact. In about four days the limb would be brought right down and the splint removed, thus allowing the patient to move his leg a little in bed. Passive movement is then carried out every day until the tenth day when the stitches are removed and collodion dressing applied; the joint is then flexed to a right angle. The patient is generally able to walk round his bed unaided on the fourteenth day, is discharged on the nineteenth or twenty-first, and is able to do full work before three months with perfect safety.

It is satisfactory to record that the above patient was discharged perfectly well on the nineteenth day.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 25, 1899.

COLONIES FOR EPILEPTICS.

Much has been written of late in the lay press with regard to the proper treatment of the epileptic. By epileptic we mean of course the sane epileptic, and for the present we will consider the matter only in this limited sense. Unfortunately, as pointed out by one writer, the law does not allow County Councils to devote money to making public provision for the treatment of the sane epileptic two courses are possible, the one is to agitate for beneficent legislation in this direction, the other is to co-operate privately so as to obtain the necessary funds for the purpose. There seems to be no doubt, judging by the results at the Home for Epileptics founded by Lady Meath at Godalming in 1892, and at two other homes in this country, that the wors

possible fate that can befal an epileptic is to be found in the same room with lunatics. That seems to be the opinion strongly expressed in the correspondence referred to. Now there are three classes to be considered here; there is the juvenile epileptic, the adult epileptic who is sane, and there is the insane epileptic. It goes without saying, and most medical men are familiar with this fact, that where there is epilepsy there is sooner or later more or less mental aberration. In the great majority of cases the aberration may be of a very transient character, so trifling as to mark a mere insignificant episode in the life history of the individual, but the fact remains that in a great many cases it is a mere stretch of courtesy to call many epileptics sane. In advancing this statement it must not be supposed that we are by any means out of sympathy with the idea that, if possible, the epileptic should be treated apart from the insane, under different, more promising, and more salutary conditions of treatment. We simply wish to point out that one must discriminate carefully so as to obtain the best results by a proper selection of cases. There can be no doubt. and those who have experience of the insane epileptic will confirm this statement, that even the insane epileptic in his lucid intervals, which are sometimes prolonged for weeks, and even months, is a most agreeable, amenable, helpful and sociable unit of the society in which he is placed. And if it is so of the insane epileptic it must be still more so of the sane epileptic, who, therefore, deserves our utmost compassion and the best efforts we can put forward for the amelioration of his condition. With regard to the juvenile epileptic, unfortunately he is too often afflicted with idiocy and imbecility as well, but there are sometimes cases of juvenile epilepsy well known to physicians in extensive practice, who have made astonishing recoveries from the disease during puberty or adolescence, and have passed through the remainder of their lives with little or no mental or nervous stigmata whatever. The treatment of the epileptic has been considered in a more generous and advanced way in Germany and America, but of late years evidence has been accumulating in this country that the public mind is wakening up to its responsi. bilities and giving more sympathetic consideration to the subject. It is earnestly to be hoped that this movement will grow, and that a differentiation will be made between the different classes, so that the proper treatment for each class of cases may be provided. The legislative machine is considerably overtaxed, yet it is quite possible that in the preparation of a new Lunacy Bill and in its passage through the Houses of Parliament a clause may be inserted giving the requisite power to County Councils to effect a real, solid improvement in the classification and treatment of the epileptic, whether sane or insane.

THE OPERATIVE TREATMENT OF MYOPIA.

SINCE Fukula revived in 1889 the method of treating cases of high myopia by removal of the lens the

procedure has acquired a large measure of popularity, and a good deal of literature has accumulated upon the subject. In the present day, however, there are not wanting signs that the inexpedient policy is being pursued of resorting to the treatment indiscriminately, and of failing to observe the necessity of selecting the cases for its practice. Under these circumstances it is easy to see that, unless proper care he taken, untoward results are bound to ensue, and, at the same time, the danger is incurred of again bringing this special form of treatment into disrepute. A word of warning, therefore, in this regard seems undeniably opportune. Even under the most favourable circumstances, a highly myopic eye is by no means a desirable organ upon which to operate. The condition of its tissues generally is far removed from that of the normal, and thus it comes to pass that the result of operative interference for the relief of high myopia must always largely be a matter of speculation, apart from any contingencies in the operation itself. The speculative nature of the result, we fear, is precisely the reason which is now tending to the indiscriminate performance of the operation. eagerness of the surgeon, of course, under the circumstances is natural. He is desirous of putting in practice a treatment which has resulted so brilliantly in many cases, and thus he is apt to allow his zeal to override his discretion. In such cases the disappointment attending failure is a matter which neither surgeon nor patient are likely to forget. Again, it is scarcely fair on the part of the surgeon recommending the treatment not to fully represent to the patient the risk associated with its practice. In appearance, perhaps also in fact, nothing is easier than to needle a lens; nevertheless, it is well known that eyes have been lost by suppuration after this simple process, despite the most rigid antiseptic and aseptic precautions. Clearly, therefore, it is impossible to assert that no risk exists, although in the m jority of cases, perhaps, that may be small. In a practical and thoughtful piper upon this subject, published by Mr. Adams Frost in the December number of the Edinburgh Medical Journal, another note of warning is sounded. "It is possible," he says, "that the liability of myopic eyes to suffer from opacities in the vitreous, and detachment of the retina, is increased by the operation, but further experience is needed to determine this. In view of these facts it would seem advisable to confine the operation to one eye, at any rate until we have seen that the results remain good after the lapse of several years." Meanwhile, it is clear that the proper policy to pursue is to be careful in the selection of cases for the treatment. Given a suitable case a patient may be well advised to incur the risk of failure in view of the possible advantages in the event of success. A brilliant improvement in the vision has been many times attained at the removal of the lens in high myopia, and this has been associated with the no less advantage of enabling the patient to dispense altogether with the use of spectacles. Patients with 15 dioptres or more of myopia are much inconvenienced by the massive concave lenses which the correction of their defect requires them to wear. The relief, therefore, which they derive from the operation when it enables them to see clearly without glasses, may be readily understood. Upon the whole, then, prudence dictates caution in the adoption of this line of practice, until a more lengthened experience has been gained of its effects. While admitting that oftentimes the immediate effects have been brilliant, nevertheless it must be conceded that there is much yet to be learnt of its ultimate results. Until, therefore, this point has been determined, the operative treatment of high myopia cannot be otherwise regarded than as still upon its trial.

THE UNQUALIFIED DISPENSER

THE fatality at Heaton Norris, near Stockport, where a woman died in consequence of an inexcusable blunder on the part of the unqualified dispenser of a local practitioner, has had for effect to direct attention to the risk inseparable from the employment, as dispensers, of persons who have undergone no training to fit them to discharge the responsible duties which they have undertaken. The notice of the Privy Council has been directed by an association of retail chemists to the circumstances of the case with the object of inducing that body to initiate legislation for the purpose of placing the dispensers employed by medical practitioners on the same footing as those employed by dispensing chemists, that is to say, to prohibit the compounding of scheduled poisons save by persons possessing a pharmaceutical qualification. It must be admitted that the quasi-legal status of these unqualified dispensers is very irregular. There is no obvious reason why the regulations with which the law hedges in the manipulation of poisons should not apply to the dispensers employed by medical practitioners, indeed the privileged position occupied by the latter in respect of the certification of death has been suggested as of itself a reason for insisting on special pre-This argument is not without weight, although, as this very instance shows, medical men would be unlikely, as well as extremely ill-advised, to attempt to hush up an accident of this kind. Still, if a qualification be thought necessary for the protection of the public in chemist's shops and open surgeries, it does not appear less necessary in private surgeries. The employment of such persons is not authorised by law but is established by long custom. As a matter of fact, the point, as far as we are aware, has never been raised before the General Medical Council, but one result of the communication which has been forwarded to the Privy Council may well be a request for the opinion of the Medical Council on the ethics of the question. Should this forecast prove correct, what is likely to be the attitude of the Council? We cannot without difficulty imagine the Council formally endorsing and approving the employment of persons

who have not undergone any training in the manipulation of poisons, and whose knowledge of drugs and their doses may be, and probably usually is, of theslightest. Nor could the Council disclaim its responsibility in the matter, which is essentially one for its: consideration. Should the matter come officially before the Council, especially if it be brought forward from high quarters, we apprehend that regulations of some kind would have to be made. It is extremely unlikely that any legislation will be initiated of the kind for which the Privy Council is now asked tostand sponsor, but the General Medical Council might conceivably prohibit the employment of persons as dispensers unless, if medical students, they had passed the examination in materia medica and pharmacology, or, in respect of others, unless they possess a certain minimum qualification in pharmacy. It must be admitted that accidents of this kind are extremely rare, but as only fatal cases are ever likely to become public there are no means of knowing to what extent public safety is jeopardised or compromised by the dispensing of medicines being left in the hands of unskilful and possibly ignorant persons. On general principles when we spy a danger we take such precautions as may appear necessary to prevent mishaps without waiting for mishaps to occur. We must not forget, however, that any sudden change in this direction would dislocate the practice of medicine throughout the land, for it would be no easy matter to replace the thousands of unqualified dispensers who at present discharge these humble but responsible functions-The matter, however, was certain to demand solution sooner or later, and very few catastrophes of the kind which furnishes the text of this article would suffice to awaken public opinion on a subject in which the public are primarily and immediately concerned.

Aotes on Current Topics.

Catching Cold.

THE old-fashioned cold has been ousted to someextent from its former position in domestic medicine by the more modern influenza. An attack of influ enza is a much better excuse for non-attendance at the office or shop than a cold, the latter being commonly regarded as an accommodation bill drawn by laziness on idleness. There is unquestionably such a thing as a cold, that is to say, a deviation from health obviously consequent upon, and due to, exposure to The initial sensation of cold is cold and damp. followed by more or less pronounced physical discomfort, possibly by more definite signs and symptoms of bronchitis or other disease a frigore. With that predilection for inexorable logic which characterises the undiscerning, the average citizen regards every illness commencing with a chill as a cold, losing sight of the fact that there are chills, i.e., sensations of cold, which are in no wise due to the action of low temperatures. This vulgar error has been productive of serious consequences in more than one direction. Take or instance, the case of the parturient Mrs. Smith up to

twenty or thirty years ago. Two or three days after having presented Mr. Smith with an addition to his family, she shivers, and is forthwith declared to have caught a cold, for which Mrs. Gamp, who is in charge of the case, is probably blamed, though she protests with the energy which characterises most of her utterances, that she is at a loss to explain how this has come to pass. Mrs. Smith gets worse, and ultimately dies or passes many weary weeks on a sick bed, all on account, says the vox populi, of a cold. Thenceforth, it is laid down as a cardinal maxim in dealing with these cases, that fresh air $qu\hat{a}$ cold air must at all cost be excluded from the lying-in The results were most disastrous, and, chamber. indeed, could hardly be otherwise, for the prevailing stuffiness of the chamber, the too-copious use of hangings to ward off draughts, and the total absence of ventilation, constituted conditions eminently favourable to the retention and multiplication of disease-producing microbes, from the effects whereof, and not from cold, the unfortunate Mrs. Smith succumbed or not as the case may be. Nowadays, and rightly, we are all for fresh air. We fear no foe save the ubiquitous microbe, and we fight him with fire and poison, with results that amply suffice to justify this war d l'outrance. It may, on the other hand, te a person with a weak chest who experiences a "chi'l" and, as it is theoretically impossible ever to exclude the influence of cold, he or she attributes the symptoms which follow—the cough, the sweating, the expectoration, &c., to incautious exposure, whereas this chill merely heralded a rise of temperature incidental to an outburst of tuberculous disease. It would surprise many intelligent people to be told that a chill is a sign that there is fever, and that sweating is usually a sign that the fever is abating. Yet such is the unvarnisted fact, and it would be well for it to be generally known. Cold is merely a debilitating agent, the effects whereof will vary according to the individual. It throws a strain on the organic machinery and the weakest part gives. machine as a whole is in good trim, nothing happens beyond a little temporary discomfort. In a rheumatic person it may determine pains in the joints; in another, bronchitis; in a third, kidney trouble; and so on-in short, it picks out the weak spots, and converts weakness into disease. Colds are notoriously infectious and the places where colds are most frequently caught are places where ventilation is defective and where microbes abound, as in theatres, churches, railway carriages, and the like, so that even the symptoms of the old-fashioned cold are for the most part the result of microbial infection and not of exposure.

The New Asylum for East Sussex.

THE East Sussex County Council have now advanced so far in the practical contemplation of the erection of a new asylum that we are able to form some conception of its size and arrangement. In approaching the consideration of this scheme they have been largely guided by Dr. Hayes Newington, as he is specially qualified to advise in matters of

this kind from his long experience of lunacy and lunacy administration. As a preliminary, it appears that a Committee of Council has made a most exhaustive inquiry as to the best methods of construction, administrative arrangement, and treatment in vogue in other asylums, notably in the newer asylums of England and Scotland. Thereafter a report was drawn up giving a summary of the results of inquiry and inspection, with recommendations as to the best means of achieving the best results. A few days ago the County Council by an unanimous vote homologated the action of their committee, and we endorse the remarks of Mr. Campion, the chairman of the visiting committee for many years at Hayward's Heath, that in taking up the matter so heartily, and in passing the committee's recommendation so unanimously they had behaved in a patriotic and noble way. Mr. Campion also paid a high tribute to Dr. Newington, who brought the members of the committee into connection with a great many doctors and others skilled in lunacy matters both in Scotland and England. Dr. Newington, with his usual zeal and energy and common sense, has brought the preliminary stage of matters to a most satisfactory conclusion, and the County Council are to be congratulated on having had his rare experience and judgment in these practical matters. As he points out, the ideas in the report circulated in the beginning of last year have been faithfully carried out as to the principal facts and in many matters of detail. The principal idea here is to break up the great mass of insanity such as in many asylums in the past had been huddled together. Provision will be made separately for those cases which have a chance of recovery, and also for the proper treatment of the sick and infirm. Into the many improvements we need not enter, but it is evident that little that is new in asylum management has escaped the observation of the management, and we recognise in the width of Dr. Newington's scope of investigation a wide unprejudiced view, from which he has carried into practical effect all that is good and excellent in the lunacy administration of to-day. We shall look forward with interest to the further development into stone and lime and actual working of this new scheme.

The Lunacy Commissionership in Scotland.

In a few weeks a change will take place in the personnel of the present Scotch Lunacy Commission by the retirement of Dr. John Sibbald who has been on the Board as deputy and full commissioner for nearly twenty-nine years. It is a critical time in the history of Scotch lunacy administration, for Dr. Sibbald has been identified with all the best features of the so-called Scotch lunacy system. Since he became superintendent of the Argyle Asylum nearly forty years ago, Dr. Sibbald has never been a place seeker, nor has he put himself much to the front for the sake of mere personal promotion, and it is to be regretted that there are not more men of his stamp, actuated by the highest principles, charged with indefatigable industry, and a vigilance and enthusiasm which dis-

tinguishes him to the last. He has never slackened his pace for work and to-day is as keen on the scent of new developments in lunacy administration and treatment-perhaps even keener than he was thirty years ago. This is saying a good deal for his virility and conscientiousness and it makes us feel all the more regret that an inappreciative Government has not extended his time service. If Dr. Sibbald had been forward in his own interest, he might by his importunity have forced upon the Government a due acknowledgment of his claims; he has been one of the quiet, undemonstrative workers who have achieved a great deal, for the like which other men would have been quick to claim the reward. The policy of the Scotch board has been largely decided by Dr. Sibbald, and his level-headed way of looking at things, his finely balanced and careful judgment, his impersonal sense of justice, have done much to raise the board in the esteem of all who have been engaged in this special department whether in the higher or lower walks of the lunacy work in the country. In determining his successor, Lord Balfour of Burleigh, the Secretary of State for Scotland, has undoubtedly a delicate task, and it is not our purpose to say anything of any of the individual candidates, but we fervently express the hope which is agitating this special department of medicine, that not only in the interest of Scotch lunacy. but of the general lunacy administration of the kingdom, Lord Balfour will exercise the wisest judgment and be happy in his choice of a successor to Dr. Sibbald. We express what we are sure must be the unanimous feeling of this special branch of our profession, that all good wishes go with Dr. Sibbald into his retirement, and that it will be exceedingly difficult to find such a man for such work again.

Syphilis in the Army: 1812 and 1896.

In a little monograph on "Syphilis among British Troops-Portugal 1812, India 1896," Dr. George Ogilvie has brought together some very interesting facts, which should be read by everyone who has the interest of our Army at heart. It has evidently already borne fruit, judging from the fact that the subject for the next Parkes' Memorial Prize will be, the "Prevalence and Prevention of Venereal Diseases in the British and Indian Armies." The author proves beyond doubt that Fergusson's statement of the gradual self-extinction of syphilis in the Peninsula is a mere fable, and it follows, therefore, that all theories built upon this assumption are worthless He also gives prominence to the fact that Fergusson himself discovered some years later that the cause of his deplorable experience in Portugal was injudicious reatment, and with commendable candour he himelf published this fact in 1843. Dr. Ogilvie further points out that a similar cause may possibly be operative in India. He is, however, careful to state that "the term treatment must be taken in its widest sense, not merely as a question of an under, or an overdose of mercury, but as comprising all the means to effect a cure, especially hygienic measures and conditions." He adds :- "little weight ought

to be attached to all suggestions of particular modes of administering mercury, such as injections. &c., which, in preference to all others, are supposed to solve this deeply-rooted difficulty." Perhaps now as formerly, as Fergusson points out, "the error lies in the abuse, not in the use of the mineral." An exhaustive inquiry into the whole details of the treatment, and the hygienic conditions is therefore necessary. It is sure to bear fruit if carried out in the spirit of unselfish veracity which made Fergusson lay aside all convenient theories of self-exhaustion of the disease in Portugal, and place the calamities occurring among English soldiers at his own door

The Punishment of Abortionees.

It may be an optical delusion but it is difficult to resist the conclusion that trials for attempting to procure, or for precuring, abortion were never so frequent as at the present time. Hardly a day passes but the subject is brought to one's attention in the daily press, and the greatest interest is evidently taken in these gruesome dramas by the reading public. One point cannot but challenge attention, namely, the immunity accorded to women at whose guilty solicitations the accused persons have lapsed into crime. There is no legititimate excuse for the inaction of the police in this The law defines the responsibility of the matter. woman without any ambiguity, but we cannot recall an instance in which she, perhaps the most reprehensible of the two parties to the offence, has ever been prosecuted. There have been several cases lately in which persons who procured or sought to procure abortion have been duly punished, while his or her partner in crime has been allowed to escape scot free. If it were brought home to such women that the very act of soliciting anyone to commit this crime is in itself punishable by a term of imprisonment, they would possibly display less alacrity in inciting others to forfeit character and liberty on their behalf, Every medical man has to decline such overtures many times a year, but while we can hardly go so far as to suggest that they should give applicants for abortion into custody, we most certainly urge upon the authorities the propriety of instituting proceedings whenever the solicitation has become a matter of public notoriety.

Hospitals and Rates.

A motion is shortly to be brought before the London County Council by Mr. J. B. Porter to exempt the eleven large general hospitals of the metropolis from the payment of rates, which at present absorb a sum of £8,000 per annum. While one cannot but sympathise with the spirit which prompts the proposal, we question the justice and expediency of saddling the ratepayers of particular parishes with the rates of the hospitals which happen to be within their limits. The general hospitals of London are by no means merely local institutions. They receive as out, and as in patients, not only the inhabitants of neighbouring parishes, but from a large area of the country around, and there is no obvious reason why the local ratepayers should be

called upon to contribute to their medical needs. The payment of rates is a disbursement which differs in no essential respect from other expenses incidental to hospital management, and no valid reason has yet been put forward why rates should be treated differently from any other of the many items of hospital expenditure. A moderate measure of reform in the out-patient departments would at once place the finances of the large hospitals on a sound footing, and we are not anxious to remove an incentive thereto.

The Rowland-Nugent Impersonation Case.

It is somewhat reassuring to those who still retain any hope of the future consolidation of the profession of medicine into an united body of men with well recognised rights, privileges, and responsibilities to note the wave of indignation that has swept through the lay Press anent the recent sentence upon the man Rowland for personation. So great has been the earnestness shown that it even suggests the possibility of the outside public being one day roused to take an interest in the question whether their lives and limbs shall be entrusted to ignorant quack or to skilled professional handling. But do these lay editors, who wax eloquent with indignation over Rowland's iniquity, reflect that it is mainly through the agency of their own columns that quackery gains the ear of the confiding crowd? What is the alternate distinction between Rowland and, say, a charlatan who calls himself "Doctor" on the strength of a bogus American diploma, and who advertises to cure cancer or who sends abortifacients to all and sundry? What, indeed, except that the one has, so to speak, "gone the whole hog," and by felony secured a registrable diploma, which the General Medical Council proceeded to place on its Register, apparently with touching confidence in human nature generally, but with entire mistrust of the adverse official warning conveyed by the Medical Defence Union. Now, for a little constructive criticism. Let Rowland work out his three years, and be thankful that his two terms of penal servitude run concurrently. Let the General Medical Council devise some commonsense means of protecting the Register; let the Medical Defence Union go to work with renewed vigour; let the lay newspapers cut out quack advertisements. Then-well-then let the general practitioner pluck up heart and organise.

Hospitals Great and Hospitals Little.

A CERTAIN section of the philanthropic world has, of late years, advocated a pernicious favouritism of the large hospitals to the exclusion of the smrll. They are forgetful, seemingly, of the fact that most of the institutions now famous and flourishing once had their humble origin, although they ignore the circumstance just as carefully as the Hebrew millionaire omits any mention of his Whitechapel ancestry. This policy of neglecting the smaller hospitals has been adopted more or less by the Hospital Sunday Fund, but not by the Hospital Saturday Fund. A gross instance of the same tendency was shown last

week in the London County Council, where a member gave notice of his intention to move that the eleven great general metropolitan hospitals should be exempted from the payment of rates. Why stop at eleven? Why not every charitable medical institution in the metropolis? Of a truth the great hospitals and the great philanthropists know how to pull the strings! So far as the medical profession is concerned the competition of the large general hospitals is disastrous, and now that at least four of them take money for their services, the evil is likely to increase like a rolling snowball in a not distant future.

The Care of School Children.

ONE of the chief characteristics of the modern conscience is the recognition of the paramount duty of the protection of the child. As in all great national readjustments, however, the generation and growth of the good seed must necessarily be more or less a matter of time. That has proved the case emphatically in the case of the disabled classes of the Pauper Metropolitan School Children, but perhaps the carrying out of the Departmental Order is one of the great social measures for the coming session foreshadowed the other day by Sir Michael Hicks Beach. Now that we have compulsory education and board schools the necessity of some kind of systematic medical supervision of the scholars has every year become more and more apparent, while suspicion as to the agency of school life in the spread of communicable diseases has been deepened into certainty so far as the incidence of diphtheria is concerned, There can be no doubt whatever, that our treatment of the board school lags far behind that of several continental nations. For instance, as recent writer on the subject has pointed out, it Brussels every school child is medically examined once in every ten days, when eyes, teeth, ears and general physical condition are overhauled. If the child looked weak and puny, cod-liver oil and other appropriate remedies are promptly administered. At mid day a square meal is provided, partly by private benevolence and partly by the commercial funds. In short, the greatest care is taken to see that no child is ill-shod, ill-clad, or ill-fed. We wonder how long it will take Great Britain to rise to this standard of humane foresight, and to provide for the bodies as well as the brains of the children of the poor.

A Curious Inquest

An inquest which presented some unusual features was held last week at Liverpool on the body of a lieutenant in the Royal Niger Company's service, who had died at the infirmary from the effects of gunshot wounds, stated to have been received in a skirmish with natives on the West Coast of Africa, though of this there was only hearsay evidence. An open verdict was returned, but the peculiar circumstances suggest the question whether an inquest is usually held to be necessary in all cases of death within a year of the receipt of wounds received in war-

fare. If not, why not? There must be many deaths every year—at Netley, for example—of soldiers who ultimately succumb to their wounds, yet we have never heard of an inquest being held to determine the circumstances under which the wounds were inflicted. We know of nothing in the law regulating the holding of inquests which would exempt soldiers from its operation. Perhaps some member of Parliament would ask the question with the view of elucidating a point which might conceivable acquire considerable importance under special circumstances.

Gloucester and Vaccination.

WE notice that the anti-vaccinationists of Gloucester have boldly announced that the recent epidemic of small-pox has had no effect upon them beyond making them more determinedly anti-vaccinationist than ever. Intelligent persons of the general community will only be disposed to feel contempt for such individuals, whose courage, in many cases, oozed out of them during the epidemic to so great an extent that they found it necessary to have some vaccine injected into them for fear that they might contract small-pox. It was a fact that in Gloucester many of the anti-vaccinationist party voluntarily submitted to vaccination while the epidemic was laying a violent hand upon the deluded community who had followed their fatal teaching. The Gloucester "delusionists" are now also proud of the fact that during the quarter ending September last, out of 415 births there were only twelve vaccinations-less than 3 per cent., and they have, in addition, stated that none of them made any application for exemption under the conscientious clause, and that they have no intention of doing so. Of course, it goes without saying that the antivaccination party in Gloucester feel exceedingly well satisfied with themselves, and they are likely to remain so, until the next epidemic comes and compels them to submit to vaccination.

The Liverpool Tropical Diseases School.

THE School for Tropical Diseases at Liverpool is now practically established, and it is significant of the policy pursued in its organisation that everyone concerned therein appears to be satisfied. Regret can, therefore, only be expressed that Mr. Chamberlain has not so far used his influence to bring about a similar result in regard to the Tropical Diseases School scheme in London. Had the Colonial Secretary wisely submitted the scheme to competent authorities in the medical world instead of permitting himself to be guided in the matter by a body of laymen representing a local charity, there is no doubt that the London School for Tropical Diseases would have been just as successful in its inception as that at Liverpool has proved. There is, however. still time for Mr. Chamberlain to remedy his error of judgment. His only wish, no doubt, is to see the scheme carried out to the best advantage. But the only way of achieving this result is to place it upon a proper footing and then secure for it the confidence of the medical profession.

A Disgraceful Affa r.

AT an inquest held before the Coroner for Lambeth, early last week, it transpired that in response to a message sent to a certain "Medical Hall," an unqualified person named Bloomenthal, apparently the proprietor of the concern, visited the person and supplied medicine. Later on in the day a lady called, and finding the patient in a bad way, fetched Mr. Neville Holland, described as M.R.C.S., and L.S.A., who diagnosed fracture of the bip, being, it is asserted, at the time, under the influence of drink, an assertion which he does not appear to have contradicted. The Coroner, at the instance of the jury, strongly censured Mr. Holland, whose conduct will be reported to the General Medical Council, while the attention of the Apothecaries' Society will be directed to that of Mr. Bloomenthal. It is a mystery how so many unqualified persons contrive to go on practising medicine year after year in flagrant defiance of the penalty recoverable under the Apothecaries' Act. One would expect neighbouring practitioners, who cannot well be ignorant of the character of these concerns, to call attention thereto, yet this seems to be but rarely the Mr. Holland has already been two years off the Register for "covering," and if this new offence be proved against him, it will go hard with him.

A Windfall for the Hospital Sunday Fund.

THE Council of the Hospital Sunday Fund learnt something very much to their advantage at their meeting last week. The announcement was made that a late resident of Brighton, Mr. William Vokins, had bequeathed a sum of £50,000 to the Fund, which would be paid over on the death of his wife. From this it may be assumed that the testator possessed some confidence in the mode in which the Fund is administered, and the Council may, therefore, regard his action in the light of a compliment to themselves. That a sum of this magnitude should have been given for the purpose of benefiting the hospital charities in London is an especially noteworthy fact, and, of course, it imposes a great responsibility upon those whose duty requires them to administer it in order that the wishes of the testator may be duly carried out.

Metropolitan Hospital Saturday Fund.

THE delegates of the above excellent body last week made their list of awards, amounting to the respect. able sum of £17,030. It is a matter of some regret that this year shows a falling off to the extent of £500, while last year, again, was £600 less than that of 1897. To some extent, however, these deficiencies may be attributed to temporary causes. We note that the largest grants have been made to the great general hospitals, several of which have received enormous sums from the public in recent years. It would be more reassuring to the medical profession and to the public if the Hospital Saturday Fund could announce that distribution was made with a constant eye to economy of management and to the curtailing of indiscriminate charity. Again, what is the attitude of the Fund towards the payment by patients which, in defiance of professional opinion, was last year adopted by the London Hospital? Mr. Acland, the chairman, has done a vast deal in fostering sound principles in this most important body. There is a still greater field before him in helping to secure justice in the relations of the medical charities to medical men.

Salicylate of Bismuth.

INVESTIGATIONS undertaken by a French pharmacist on the salicylates of bismuth tend to prove that the composition of these salts is far from uniform. Many of them, it is stated, are not, properly speaking, salts at all, but merely molecular combinations of bismuth oxide and salicylic acid. The fact that the salicylic acid is washed out of these so-called salicylates in direct proportion to the solubility of the acid in the solvent employed supports this view. Some of the samples proved to be mere mixtures of subnitrate of bismuth and salicylic acid. It is quite possible that this mixture may produce the effects expected of the salicylate salt of bismuth, but even if this be so it would be better for the prescriber to specify the proportions of the two constituents rather than leave this important detail to the whim or caprice of the manu'acturing druggist.

The Wrong Tooth!

An extraordinary action was tried at the Wolver-hampton County Court a few days ago, when a stable lad claimed £25 damages of Mr. Bebb, a medical practitioner, for having extracted the wrong tooth. It transpired that there was a bony growth at the root of the aching molar which projected beneath the adjacent one, dragging the latter out at the same time. The judge, of course, gave judgment for the defendant with costs. There are probably a large number of people who would be willing to have their teeth extracted at £25 apiece without costs.

The Royal College of Surgeons and the Members' Gown.

As might have been anticipated the Council of the Royal College of Surgeons of England has adjourned the consideration of a gown for members sine die, a very appropriate way to dispose of a suggestion which was simply ridiculous on the face of it. Gowns and stuffed alligators as appurtenances of the consulting room belong to a bye-gone age, and we have no wish to rescuscitate them.

The Guernsey Way of Dealing with Quacks.

A PERSON called Derentz, who was banished from Guernsey five years ago for malpractices, was summarily arrested last week and lodged in gaol, where he unsuccessfully attempted suicide. He is suspected of being in the habit of receiving young women in his house for the purpose of procuring abortion, keeping them under his charge until convalescence. Derentz is generally known as "the doctor," but possesses no medical qualification.

British Hospital for Rome.

THE MEDICAL PRESS.

THE British colony in Rome have decided to found a hospital in the city for the benefit of English persons. The estimated cost of the erection and equipment of the institution is £7,000, of which sum only a small proportion still remains to be raised. The hospital, it is expected, will be ready for patients early next year.

A HERBALIST, named George Hare, 69, was found guilty of using an instrument with intent to procure abortion, and at the Old Bailey last week was sentenced to twelve years' imprisonment. In 1889 he was sentenced to a term of ten years' penal servitude for a similar offence.

ACCORDING to the report of the Medical Officer of Health for the parish of Stoke Newington, published last week, the recorded death-rate of the parish for the four weeks ended December 31st, was only 10.8, while that for the whole of London during the same period was 17.2.

LADY ELGIN opened the Lady Dufferin Victoria Hospital in Calcutta, last month. The building cost three lakhs of rupees, the bulk of the money having been subscribed by native gentlemen.

PERSONAL.

SURGEON-GENERAL H S. Muir has been appointed Deputy Director-General of the Army Medical Service.

SURGEON-GENERAL W. TAYLOB, C.B., has been appointed Principal Medical Officer in India.

SURGEON-GENERAL W. S. M. PRICE has been appointed Principal Medical Officer with the British Forces in Egypt.

MR. ALEXANDER G. R. FOULEETON, F.R.C.S.Eng., D P.H.Camb, F.C.S., has been appointed Bacteriologist to the Middlesex Hospital.

Dr. Robert Barnes and Mr. Lawson Tair have been elected Honorary Presidents of the Gynæcological Congress, which is to meet at Amsterdam in August.

H.R.H. THE PEINCE OF WALES has announced his intention of being present at the Hunterian Oration at the Royal College of Surgeons, England, on Tuesday, February 14th next.

THE President of the Royal College of Surgeons in Ireland entertained at his residence on Thursday last the Councillors of the College, with the addition of Sir Thornley Stoker and Dr. James Little.

Dr. N. H. Chokery, medical officer in charge of the Arthur Road Hospital, Bombay, has been invested with the Order of the "Crown of Italy," by command of the King of Italy. The decoration was presented to Dr. Chokey for services rendered to the Italian representatives of the plague commission who visited India last year.

Dr. Molony, F.R.C.P.I., Senior Resident Medical Officer of St. Patrick's Hospital, Dublin, has accepted the offer of the Governors to take charge of the newly acquired country branch at Lucan. The vacancy thus created has been filled by the appointment of Dr. Robert Richard Leeper, at present Surgeon to the Rathdrum Union Infirmary, and Visitor of Lunatics under the Lord Chancellor. Dr. Leeper's contributions to psychological literature are well known.

Correspondence

We do not hold ourselves responsible for the opinions of our correspondents.

PRIMARY EPITHELIOMA OF THE UVULA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,—Regarding your interesting note of Dr. Walker Downie's case of this nature reported in the current number of The Scottish Medical and Surgical Journal, you rightly say that it "is a very rare affection."

On referring to the original report, I find that Dr. Downie quotes from the third edition of my work, "The Throat and Nose, and their Diseases," to the effect that I had up to that time not seen an example. This is true, but in my fifth edition, on page 322. I report an example as Case XXVII, that of a male patient, et. 48, who was first seen by me on the recommendation of Dr. Watson, of Tunbridge Wells in June 15th, 1897, just a month before the date of Dr. Downie's case. The result of excision has been equally satisfactory, nineteen months having elapsed without recurrence. The coloured drawing of the appearance is given on Plate V., Fig. 37, and a microscopical section on page 323, as Fig. CLXIX, which showed the growth to be of the squamous variety of epithelioma.

I am, Sir, yours truly,

LENNOX BROWNE.

Mansfield Street, W., January 20th, 1899.

specialistic attitude.

POPULAR BACTERIOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR, - In reference to the remarks contained in your last issue under this title, I beg to say, in the first place, that the writer nowhere makes it apparent that he bases them on material taken from three different sources. Of these, the first, which contains my repudiation of any desire to pose as a specialist, appeared in the Lancet of December 10th, and deals exclusively with the therapeusis of diphtheria, upon which point my experience, I repeat, does not justify my assuming a

The question of my appointment as bacteriologist rests upon an entirely different footing. I have no wish to boast, but, having devoted most of my spare time for the last ten years to this class of work, and having been sufficiently fond of, and interested in, it to maintain a laboratory at my own expense for the last seven years for its study, my claim might reasonably be a different one.

The lecture was not a public one, but was delivered before the members of the Camberwell Vestry, and such medical men as accepted the Vestry's invitation to attend. It was reported, most inaccurately, in the Daily Telegraph of the following day, and the report in question has been taken by your contributor as the basis of his criticisms, a very rash, as well as a very unfair proceeding. The time devoted to diphtheria may have been ten minutes out of eighty, and the absurd statement as to the relative virtues of vaccination and antitoxin (even the Telegraph did not limit me to diphtheria in this connection, as your contributor does) really amounted to no more than a statement of the possibility that vaccination, which only provides prophylaxis against one disease, might in the long run, prove to be

a less important discovery than that of antitoxin, which opens an entirely new avenue in medical research, since it indicates a possible method of treatment of all infectious diseases upon the same lines. It was not thus, a question of the benefits that have accrued from the small amount of work that has been done, but of the enormous possibilities of the method.

The third source of information of which your contributor has availed himself is the "interview" in the South London Press of last Saturday. This journal having copied the Telegraph verbatim, I wrote to the Editor, and he sent down a reporter, who naturally availed himself of the opportunity of acquiring further information, as well as making the corrections which I insisted upon. The statement as to the reduction of mortality from diphtheria in Camberwell occurs in this, and I am at a loss to see what there is in it to which exception can be taken. Does your contributor deny my facts or my figures? That I have counted my chickens before they are hatched—or shall we say, killed?—is untrue. I have been set to work to assist the Vestry in reducing the mortality, and the figure mentioned is what we aim at. Unfortunately, I know only too well that the chances are a thousand to one against its being attained at present, since I know the difficulty which will be experienced in bringing home to medical men their duty in the matter. If we could do this, we should reduce the mortality to three per cent., and save 120 lives annually on the population of Camberwell, which is over a quarter of a million.

I have never yet heard it claimed for glycerinated lymph that it was absolutely sterile, nor was this my point. The hope I expressed was that we might be able to supply lymph in a form which would "satisfy the conscience of the most conscientious objector," since, being manufactured in vitro, it would be free from any suspicion of animal contamination. Anyone who has had much to do with the conscientious objector knows that this point is the real "refuge for the destitute" of the anti-vaccinationists.

Finally, may I suggest that your contributor, in denying the possibility of the extinction of infectious disease, in reply to a conjecture of mine, is venturing into regions of prophecy into which I, for one, am disinclined to follow him? That is what is being simed at, and the progress made in this direction, and the increasing number of means available in the conflict, justify the hope that -though not in our lifetime-this may be accomplished. Your contributor may, however, comfort himself with the reflection that, whichever of us is in the right will never be able to enjoy the triumph, dear to the heart of every Englishman, of saying, 'I told you

I am, Sir, yours truly, EDWARD C. BOUSFIELD.

363, Old Kent Road, January 20th, 1899.

INACCURACIES IN THE MEDICAL REGISTER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—Now that the question of the accuracy of the Medical Register is being ventilated, it may interest you to know that I recently accidentally discovered several errors in it. One is that of a friend of mine who has been dead for several years, but his name and address in a foreign town still figure in the Register of 1898. The name of his father who died more recently has, however, been removed. Three or four practitioners in this town are apparently liable to have their names erased as their addresses are totally wrong, and another friend of mine, who has practised in London for several years, is still officially located in the Royal Infirmary, Edinburgh.

officially located in the Royal Infirmary, Edinburgh.

These are merely random samples of inaccuracy from one cause or another, and doubtless many others could be added thereto.

I am, Sir, yours truly,

M. 8.

Cambridge, January 23rd, 1899.

PERSONATION AND ERASURE FROM THE MEDICAL REGISTER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

Sir, - May I point out that the periodical erasure of the names of registered practitioners who do not respond to the Registrar's roll-call affords no protection whatever against personation. The personator would of course take care to acknowledge receipt of the notice, and as the Registrar has no means of testing or controlling the authenticity of the signature, the fraud necessarily escapes detection.

I am, Sir, yours truly,

G. S. A.

MEDICAL SOCIETY OF LONDON.

At the meeting on Monday evening last (January 23rd) Mr. CUTHBERT WALLACE read notes of three cases of appendicitis with diffuse peritonitis in which he had successfully operated. In two instances the peritonitis was general, but in the third it did not extend beyond the transverse meso-colon. In all three he had removed the appendix and turned out the intestines, flushing the belly cavity with sterile water. He made his incision through the right rectus muscle. All three cases recovered without a bad symptom.

In the discussion that followed the author was warmly congratulated on his unprecedented success. Mr. Clutton referred to the bad results which formerly followed ex-ventration, but thought it might be revived with advantage. To obviate the difficulty in getting the bowels to act he recalled a suggestion to inject a solution of magnesium sulphate into the bowels high up by means

of a hypodermic syringe.

Mr. STANLEY BOYD questioned the accuracy of the description of diffuse peritonitis in many of the recorded cases. He had inquired for a drug which would act on the bowels if injected hypodermically, but had not been able to find one. It must be impossible, under any circumstances, absolutely to cleanse the peritoneum, and much must depend on the patient's powers of resistance.

Mr. Bruce Clarke thought ex-ventration was, on the whole, a good thing, and he approved of the incision through the rectus.

Mr. Battle mentioned a case of diffuse peritonitis in

which he had operated.

The President insisted on the prognostic value of

thoracic breathing and abdominal hardness.

Mr. P. J. FREYER related "two recent cases of successful operation for impacted stone in the ureter." first case was that of an officer, æt. 23, who had suffered from renal colic and hæmaturia for nineteen months. He exposed and incised the kidney, but found no stone. He found one, however, impacted four inches down the ureter, and he incised the ureter and removed the stone. The patient made a perfect recovery. In the second case, a man with multiple stricture had suffered for many years from symptoms of kidney stone. The left many years from symptoms of kidney stone. The left kidney was explored by another surgeon in 1895 without result, and on his re-exploring no kidney could be found. He subsequently performed internal urethrotomy, still without affording relief. Later on, with the cystoscope, he detected a stone projecting from the right ureteral orifice into the bladder, and this he removed with the lithotrite, after which the patient gradually recovered.

Mr. BRUCE CLARKE related the case of woman from whom he had removed a stone impacted five inches down

the ureter.

THE SWINEY PRIZE.

THE adjudicators of the Swiney prize, at the meeting held in the rooms of the Society of Arts on Friday the 20th inst., awarded the prize for the present year to Dr. J. Dixon Mann, F.R.C.P., Professor of Forensic Medicine and Toxicology in Owens College, Manchester, for his work on "Forensic Medicine and Toxicology." The prize, in accordance with the will of the testator, is awarded on every fifth anniversary of his death to the author of the best published work on Jurisprudence. The prize consists of a silver goblet of the value of £100, with money to the same amount. Dr. Swiney died fifty

years ago-on the 20th of January, 1844-and the award has been regularly made every fifth year to the present time. The Society of Arts are the trustees of the fund, and the award is made by that Society and the Royal College of Physicians of London. Having regard to this fact, the prize has up to the present date been given alternately for works on General Jurisprudence and on Medical Jurisprudence.

SIR WILLIAM McGregor, who has just been appointed Governor of Lagos, is M.D. of Aberdeen, but he early developed such striking administrative abilities that he does not seem to have practised his profession to any great extent. A medical education must, however, be valuable even to the governor of a colony.

THE Duchess of Albany last week opened the new Nurses' Home of the Chelsea Hospital for Women, and afterwards paid a visit to the hospital.

Obituary.

MR. ARTHUR HENRY WILSON, OF LIVERPOOL.

WE sincerely regreat to have to announce the death of Mr. Arthur Henry Wilson, which took place at his residence. 30 Rodney Street, Liverpool, on January 15th, in his 39th year. The deceased, second son of Mr. C. B. Wilson, an old and highly respected surgeon of that city, had a distinguished career as a student, gaining the Lyon-Jones scholarship and gold medal in anatomy, and the Derby Exhibition in clinical medicine. Later he filled the offices of house physician and house surgeon at the Royal Infirmary, Liverpool, where his father had also been house surgeon in his early days. Commencing private practice he was appointed honorary surgeon to the Stanley Hospital, Liverpool, and some years ago he received the appointment of surgeon to the Northern Hospital, which post he retained to the time of his death. Rather reserved in manner, he did not court friendships, but those he made were firm and sure, and perhaps no one had warmer friends than Arthur Wilson. It may be truly said that those who knew him best loved him most.

As a surgeon he was able, clear-headed, and a skilful operator and his colleagues lose in him an esteemed and valued friend whose untimely end they deeply deplore. Some months ago he began to show signs of serious illhealth. At first the symptoms were far from pronounced, and considerable doubt existed as to the nature of the Later on, however, symptoms of ulcerative malady. endocarditis became evident, and to this he succumbed. The deceased was not married.

The funeral, which took place on the 18th inst., was very largely attended, the officiating clergyman being his brother-in-law, the Rev. Stephen Gladstone, rector of

Hawarden.

Literary Aotes and Gossip.

We have received the first number of a new medical review, "Les Archives Provinciales de Medécine," edited by Dr. Marcel Baudouin, Paris. Among the contents is a valuable and exhaustive contribution, beautifully illustrated with coloured drawings, entitled "Mixed Tumours of the Parotid," by Drs. Curtis and Proces, which will well repay perusal. This new publication promises well, and should prove successful.

SEVERAL of our American contemporaries, just to hand, publish some comments upon the new departure in medical journalism which has been adopted by a medical journal, recently founded in Philadelphia, of refusing to issue exchange copies. No doubt, as a piece of "bluff," the announcement of this change was, to use a vulgar phrase, "smart," and, in any other country than the United States, might prove in the end to be a successful move. But, judging from the remarks of our contemporaries, just the opposite effect is likely to ensue, as the

medical journal in question will probably, before long,

UNDER its new editor the English Illustrated Magazine has taken a new lease of life, and shows noteworthy improvement. The January number is a most interesting issue, containing many articles of the kind most likely to attract magazine readers. Moreover, a new feature has been introduced of coloured illustrations, and these are of a highly artistic and finished character. Mr. Bruce Ingram, the new editor, is to be congratulated upon the success with which he has inaugurated his assumption of office.

THE new volume, July—December, 1898, of "Braithwaite's Retrospect of Medicine" just published, well sustains the reputation of the work. The valuable series of abstracts which it contains culled from the medical literature of the past half year renders it an essential volume to every practitioner desirous of keeping himself abreast with the times. Its usefulness is further increased by an admirable synopsis which shows at a glance the various subjects dealt with.

Messes. Kegan Paul and Company have just issued a revised edition of Mr. E. A. Reynold-Ball's "Mediterranean Winter Resorts." Although the characteristic features are unchanged the requirements of ordinary tourists are more fully met than in the previous edition, and in the case of places of historic or artistic interest the principal sights are so fully described as to render the traveller independent of guide books. At the same time particular care is paid to the interests of those classes of visitors for whom the book is mainly intended, viz., invalids and winter residents, and great importance is given to the medical aspects of various winter stations.

Messes. John Wright and Co., of Bristol, have sent us a new "case paper," designed by Drs. Couch and Lancaster, which certainly offers some advantages over those in general use. It consists of four pages, the first whereof gives headings under which the various items of whereof gives headings there which the various items of information concerning the name, &c., of a patient and the condition of his organs, can be entered, thus ensuring that no essential particulars are overlooked or omitted. The two centre pages are covered with tracings in faint red of the trunk, from the front and from behind, as well as in section, feet, hands, throat, larynx, &c., on which observed morbid conditions can be readily recorded. There remains a blank page for miscellaneous notes. These papers are supplied at 26s. per 1,000.

THE "Phonographic Outlines of Medical Terms," published by the Society of Medical Phonographers is, or should be, of use to those medical students who are disposed to avail themselves of the facilities afforded by shorthand for taking notes of lectures, &c. As a matter of fact, however, this work does little more than show the easiest way in which a given scientific word can be written in full most of the outlines being, so to speak, en toutes lettres. What we should have imagined the student to require would be useful grammalogues of the more frequently used medical terms. Skilled writers of shorthand can, of course, invent these for current use as and when occasion may require, but even they might be glad of a few hints. There is an appendix containing a list of words having the same shorthand outline and distinguishable only by vocalisation or position, but in the interests of legibility we should advise the student phonographer to rely on the former rather than on the latter.

An official organ of "The International Commission on Adulteration" has just made its appearance under the title of the British Food Journal and Analytical Review. Its objects are as foreshadowed by the title, and, by its aid the Association—branches of which exist in every capital in Europe—will doubtless accomplish a good deal towards the suppression of adulteration of food and drugs. The initial number is in itself a powerful plea for its raison d'etre, and few would-be adulterators will care to be pilloried in an organ which, by reason of its official

character, will find its way throughout the civilised world. The names of members of the Commission are given in the number before us, the President being Prof. Brouardel, of Paris, and the representatives for Great Britain: Sir Hy. Thompson, Bart.,; Sir Chas. Cameron, C.B.; Prof. Corfield, F.R.C.P.Lond.; and Mr. Chas. E. Cassal, F.I.C. The journal will be published monthly by Messrs. Baillière, Tindall, and Cox.

THE "Plan and Plea for National Medicine," by E. L. Garbett, of the Peculiar People, is a protest against "the notion of a class of men learned in medicine and selling their advice" as being utterly foreign to the Old Testament. It may be that in those days no one had any medical advice worth paying for, but this is hardly suffi-cient to justify the abolition of doctors now, in favour of a birth-tax, or rather an ante-natal tax, "estimated at one halfpenny per week between the ages of 10 and 30, rising to threepence for the first year, twopence at 45, and an additional penny for every five years." In discussing the parcelling-out of the "health parish," we are directed "to multiply the number of persons in each age by that age's units of vitality, and then equalise the whole sum" —Q.E.D. The author incidentally protests against medical fees, which he (or she) regards as "percentage on outlay," and this leads her to, or from, the remark that "every farthing of interest on capital is damuable plunder of labourers," which is not exactly ad rem—but no matter!

It is rather a pity that Dr. Robert Bell's pamphlet on the safety of chloroform should be disfigured by such an intolerable amount of vehement rhetoric and abuse couched in biblical phraseology. Had he shown himself more temperate in his advocacy, and more guarded in his language, we should have congratulated him on having attacked a subject which certainly calls for atten-tion. He has set himself the task of rehabilitating chloroform as an anæsthetic, it having fallen into disgrace owing to the numerous fatalities following its use by unskilled or careless persons who are unable, or for some reason unwilling, to adopt the only means whereby this powerful agent can be safely administered, vis, a regulating apparatus of an approved type. The statistics upon which the conclusion has been arrived at that ether is a safer anæsthetic than chloroform, are vitiated by the fact that they are mostly based on cases in which ether has been given by means of an apparatus, while chloroform has been given recklessly on a towel. The carelessness in each case being presumed equal, chloroform is obviously likely to prove more fatal than ether because it is much more powerful. That ether per se is not safe, is proved by the fact that no less than fifty-four deaths have been recorded in this country from that cause during the past year.

NEW BOOKS AND NEW EDITIONS.

THE following have been received for review since the publication of our last monthly list:

BAILLIERE, TINDALL, AND COX (London, Paris, Madrid).

Dictionary of Medical Terms. Vol. I., English-French. By H. de Méric, M.R.C.S., Surgeon to the French Hospital, London. Pp. 394. Price 5s.

BLACKWOOD AND SONS (Edinburgh and London).

The Good Regent: A Chronicle Play. By Professor Sir T. Grainger Stewart, M.D., LL.D. Pp. 207. Price 6s.

JAMES BOWDEN (London).

The Secret of Good Health and Long Life. By Haydn Brown, L.R.C.P., L.R.C.S.Edin. Second Edition. Pp. 172,

J. AND A. CHURCHILL (London).

Guy's Hospital Reports. Vol. LIII. Edited by E. C. Perry, M.A., M.D., and W. H. A. Jacobson, M.A., M.Ch. Pp. 310, St. Thomas's Hospital Reports. Vol. XXVI. Edited by Dr. Hector Mackensie and Mr. G. H. Makins. Pp. 472, with additional reports on special departments. Price 8s. 6d.

W. and A. K. Johnston (Edinburgh).

The Anatomy of Labour and its bearing on Clinical Work. By A. H. F. Barbour, M.D., F.R.C.P.Ed., F.R.S.Ed Pp. 216 and 146. 2nd Edition.

SAMPSON, LOW, MARSTON, AND Co. (London).

Twentieth Century Practice. Vol. XV. Infectious Diseases. Edited by Thos. L. Stedman, M.D., New York Pp. 658.

THE SCIENTIFIC PRESS, LIMITED (London).

Poison Romance and Poison Mysteries. By C. J. S. Thompson. Pp. 255, Price 6s.

SIMPKIN, MARSHALL, HAMILTON, KENT AND Co. (London).

The Retrospect of Medicine. Edited by Jas. Braithwaite, M.D. Lond., and E. F. Trevelyan, M.D., M.B.C.P. Lond. Vol. CXVIII. Pp. 440.

SWAN, SONNESCHEIN AND Co. (London).

Sanataria for Consumptives in all Parts of the World. By F. R-Walters, M.D., M.B.C.P. Pp. 371. Price 10s. 6d.

JOHN WRIGHT AND Co. (London).

The Treatment of Disease by Physical Methods. By T. Stretch Dowse, M.D., F.R.C P.Ed. Pp. 412. Price 7s. 6d. net.

T. FISHER UNWIN (London).

Life of Man on the High Alps. By Angelo Mosso. Translated from the Italian. By E. Lough Kicsow, Pp. 342. Illustrated. Price 21s.

Literature.

LOCKWOOD ON HERNIA, HYDROCELE, AND VARICOCELE. (a)

Another work by this author cannot fail to give pleasure and instruction, and the more so since the volume before us is the writer's verdict on his own practical experience. It is the record of his operations for the radical cure of herniæ, of hydrocele, and varicocele. He well says that the operation for the radical cure of hernia has no longer to be defended, though it is, perhaps, to be desired that the expression "the operation for the radical cure of herniæ" might have given way to the less cumbersome, and less dogmatic one of "the radical operation upon herniæ." This needs no defence, because of its success, its low death-rate, and its freedom from the complication of suppuration, which latter fact we think is greatly due to the work and teaching of Mr. Lockwood. In dealing with operations upon hernise, the author divides all such protrusions into three varieties—congenital, traumatic, and acquired. We think that this is a little unfortunate, since the terms used are generally somewhat differently employed. "Congenital" is correct if by it is meant, as Mr. Lockwood does, that the hernia is due to some failure in development, but "acquired" should include all other forms of herniæ. Thus the variety "traumatic" is to be but a subdivision of "acquired," and even then should have two. meanings—namely, to indicate those protrusions which are the result of operative procedures on the abdominal wall, and those which are caused by actual tearing asunder of fibres, true "ruptures." Lockwood is emphatic that in inguinal herniæ one is only likely to secure good and lasting results in the cases of congenital and "traumatic" herniæ, and this teaching is the outcome of all the experience of those who have had a large number of cases under their care. regard to the congenital variety as it occurs in infants, he holds with many other surgeons, that a carefully adjusted spring truss will, in a large majority of the instances bring about a cure, but if it does not before the child begins the active enjoyment of athletic pursuits, then operation should be advised. His directions for the performance of the operation, after his explanation of the preparation of the patient, leave nothing to be desired. He dwells on the very important point as to the manner in which an arrested testis is to be dealt with when encountered in the radical operation. His experience of returning it to the extra-peritoneal tissue is limited to one case, but others have found but little harm to follow such a procedure in instances where the organ cannot be brought into its natural resting place. Mr. Lockwood's remarks on hydrocele, and varicocele are chiefly in connection with their complicating the operation for the relief of hernia, but the whole subject of these conditions is very carefully reviewed, especially in reference to operations for their radical cure. He advocates excision of the sac in the hydrocele, and sterilised twisted silk in ligating a varicocele. From every point of view we cannot regard this work otherwise

(a) "On Hernia, Hydrocele, and Varicocele" By C. B. Lockwood, F.R.C.S., Assistant Surgeon to St. Bartholomew's Hospital, Surgeon to the Great Northern Central Mospital. London and Edinburgh: Young J. Pentland. 1899.

than as one that will considerably help surgeone in the selection and treatment by operation of the many forms of scrotal swellings, designated by the terms hernia, hydrocele, and varicocele.

OSLER'S PRINCIPLES AND PRACTICE OF MEDICINE. (a)

New improvements in type and paper have been called in to increase the attractiveness of the present issue of this deservedly popular American text-book; the text has been in all parts revised, and in considerable proportion rewritten, so as to bring the volume abreast of the present state of scientific and clinical knowledge. These modifications were very necessary, of course, as the former edition is three years old, which appears to be the maximum degree of longevity which this progressive and unsympathetic age allows to any representative text-

book of the science of medicine.

"The following articles have been re-written or are new:-Vaccination, Beri-beri, the Bubonic Plague, Cerebro-Spinal Fever, Pneumonia, Malta Fever, Yellow Fever, Dengue, Leprosy, Glandular Fever, the Gonor-rhoal Infection, Cancer of the Stomach, the Gastric Neuroses, the Cirrhoses of the Liver, Jaundice, the Diseases of the Rile Passages, Diseases of the Pancreas, Diseases of the Thymus Gland, Diseases of the Spleen, Lymphatism, Addison's Disease, Encephaliti, Neurasthenia, Erythro-melalgia, and many other shorter articles, as Ether Pneumonia, Anæsthesia Paralysis, Pneamaturia, Albumenuria, &c.

"Into the sections on Typhoid Fever, Tuberculosis, Rheumatic Fever, Diabetes, Gout, Parasitic Diseases, Diseases of the Blood. Heart, Lungs, and Kidneys, much new matter has been incorporated. The section on Diseases of the Nervous System has been rearranged. and an attempt has been made to group the diseases in accordance with the modern conceptions of the anatomy and function of the parts."

A text-book, so well known to the professional public of the period, assuredly requires no critical introduction through the medium of our pages. Accordingly, we think it only necessary to say that the author has used all his wonted care and skill in bringing the present issue fully abreast of the most advanced lines of our scientific knowledge, and has been well seconded by the efforts of the publisher, printer, and bookbinder in their respective spheres. They have succeeded in making this admirable manual of medicine attractive in direct proportion to its instructiveness, and the net result of their "conjoint" labours is the best hand-book in the English language of its subject that we know of.

ANDERSON'S YELLOW FEVER. (b)

This little book of one hundred and six small octavo pages contains an excellent clinical picture of yellow fever, and gives the author's experiences of the disease; an experience gained in thirty four years' hard work in the West Indies.

Like all physicians of his day, Dr. Anderson went to the Tropics without any knowledge of tropical diseases, but, fortunately, for himself he formed the acquaintance of two physicians who were very competent and quite willing to instruct him in the nature and treatment of these diseases.

The book is intended for practitioners, and not for students reading for examination, and consequently there is nothing about the theories of the fever.

As a record of the author's personal experience of yellow fever in the West Indies, the book has a distinct value, and may be read with great advantage by physicians who propose practising in the Tropics. He is

⁽a) "The Principles and Practice of Medicine." Designed for the use of Practitioners and Students of Medicine. By William Osler, M.D., LL.D.Edin., F.R.S., F.R.C.P., Professor of Medicine in the Johns Hopkins University, and Physician-in-Chief to the Johns Hopkins Hospital, Baltimore; formerly Professor of the Institutes of Medicine, McGill University, Montreal; and Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia. Third edition, largely re-written. Edinburgh and London: Young J. Pentland. 1898. Medicine in the distribution, largely re-written. Edinburgh and Pentland. 1898.

(b) "Yellow Fever in the West Indies." By Izett Anderson, M.D.Edin. London: H. K. Lewis. 1898.

clear and brief in statement, telling his story plainly in idiomatic English, for which, and for the absence of padding, we are truly grateful. The number of fatal cases is less when antitoxin is used early in the illness than in those who do not receive it until a later period. The frequency of the occurrence of paralysis is not diminished, but the percentage of recoveries in cases with paralysis is slightly increased.

Rashes are produced in about one-third of the cases, and are attributable to the antitoxin. occasional swelling about the joints are produced in a small number of cases. Even when used in very large doses, no serious ill effects have followed the injection of

antitoxin.

Although we do not wholly accept these conclusions, we recognise the value of the report as a most useful contribution to the study of this terrible disease; an immense mass of facts have been collected, classified, and supplied to the reader in a form which enables him to draw his own conclusions and supplies him with a great body of information on the disease.

THE CLINICAL SOCIETY'S TRANSACTIONS. (a)

THE present volume of Transactions, which was published on October 11th last, is one of unusual interest. In an appendix it contains the "Report of the Committee on the Antitozin of Diphtheria."

To similar reports published by this great Society the medical profession and the public are much indebted.

The investigation of other medical problems undertaken by this Society have been carried out with a thoroughness that left nothing to be desired; the members who undertook the onerous task seemed to be one and all fired with an enthusiasm for scientific truth that carried them successfully through labours that would

have deterred less fervent students.

These well-known facts give a great value to any pronouncement on medical matters the Society may make. It is, therefore, of the utmost importance that no opinion will be expressed by the Society without the most scrupulous care being taken that the conclusion arrived at is based on the clearest proof. We wish we could see our way to the acceptance of the conclusions arrived at in the "Report of the Committee on the Antitoxin of Diphtheria." We have a great respect for the labours of the Committee, and we acknowledge that the subject selected for investigation was worthy of the Society's best effort for eluc dation, and that it is one of the most pressing problems in the medical world. But all this said, all of which is distinctly creditable to the Society, does not alter our opinion on the conclusions, which are as follows :-

The use of antitoxin reduces the mortality by onethird

The mortality in tracheotomy falls by one-half.

Extension of membrane to the larynx rarely occurs after the administration of antitoxin.

The duration of life in fatal cases is decidedly prolonged.

Of the thirty-six original articles in the volume we have not space to tell their value; they are all of the high standard of excellence that characterised the proceedings of the Society from its beginning, and placed it in the first rank of scientific medical societies.

We may just a ld that the work has been carried on for over thirty years by honorary secretaries; a fact which speaks eloquently of the love of medicine for medicine's

sake.

TOURETTE'S TREATMENT OF SYPHILITIC MYELITIS. (b)

This new series of short monographs—not exceeding 100 small octavo pages - has for its object to provide the student and general practitioner with such information concerning current events in medical literature as is necessary for their "examination and everyday professional work." The present volume contains a baid

(a) "Transactions of the Clinical Society of London." Vol. XXXI. London: Longmans, Green and Co. 1898.
(b) "Formes cliniques" et traitement des myélites syphilitiques Les Actualites Medicales. Paris: Baillière et Fils. 1899.

lucid sketch of the principal forms of syphilitic myelitis, their pathology and treatment, by a writer of repute and competence. Most of the illustrative cases are taken from the stock of his personal experience. This subject is familiar to all who are cognisant of the dis-cussion which occupied two meetings of the Medical and Chirurgical Society of London in February and March, 1895; yet a few points are deserving of special mention. Under the designation, "Myélite syphilitique, pseudo-tabétique," attention has been drawn by the author to cases in which the meningo-myelitic process is in the main limited to the region of the posterior roots of the cord, causing their compression by inflammatory products. Thus the picture of tabes may be closely mimicked. The author is of opinion that the rare cases of recovery from tabes after mercurial treatment belong to this category. This is hardly likely considering the difference in the clinical features of the two affections with regard to reflexes and gait. In opposition to Erb, the author has found that pupilary symptoms are pretty frequently met with in Erb's spastic paraplegis. In par-ticular, the so-called "sympathetic ptosis," due to impli-cation of the first dorsal pair, is declared to be by no-means rare. This is explained by the circumstance that even in cases of apparently only dorso-lumbar localisa-tion, the microscope nearly always reveals the whole spinal axis to be involved by the myelitic process. A separate chapter is allotted to hereditary syphilisas a cause of myelitic affections, in particular, in a dult age. According to the imperfect state of our actual knowledge on this subject it is chiefly of a conjectural and controvertible description. With regard to treatment, subcutaneous injections of mercurial salts (exception is taken to calomel) are advocated in cases of urgency, while in the more chronic forms, preference is given to the inunctions.
The handy little book is neatly got up, and well printed. Within its scope it is an altogether readable and commendable publication.

MOULLIN ON INFLAMMATION OF THE BLADDER. (a)

WE are old enough to have heard the oft-told lecture on "Catheter Fever," and we remember the serious tones in which the lecturer told of the unsvoidable risk attendant on such a simple operation as passing a catheter. Why the fever should follow in one case and not in another was, we were gravely informed, a mystery. In fulness of time the mystery has been solved, and we now know that a dirty catheter set up septic poisoning, which was attended with all the train of symptoms that are included under the name fever

It appears, however, from Mr. Moullin's monograph that there are some members of the profession still living who are not convinced of the truth of the theory that the fever is due to septic poisoning; to try and convince these doubters is the principal aim and object of the book before us. Twelve chapters are devoted to the subject, and we are inclined to think that the doubter who reads the monograph and still remains unconvinced of the truth of the theory can hardly be said to be capable of reasoning. The book well sustains the credit of the author for fulness of knowledge, and facility and clearness in teaching.

MORRIS ON RINGWORM. (b)

Or recent years a vast impulse has been given to the study of ringworm by the researches of Sabouraud, who first definitely established the plurality of fungus in that disease. In the book under review the author has treated the subject systematically and thoroughly from one end to the other, and has produced a concise, up-to-date, and accurate monograph. With practised literary skill he has drawn up a clear history of the gradual evolution of medical knowledge upon the subject. We note that he appears disinclined to follow Sabouraud in his well-nigh endless differentiation of fungi and of the distinct species

⁽b) "Bingworm, in the Light of Recent Research." By Malcolm Morris, Surgeon to Skin Department, St. Mary's Hospital. Cassell and Co., London. 1898.

⁽a) "Inflammation of the Bladder and Urinary Fever." By C. Mansell-Moullin, M.D.Oxou., F.R.C.S. London: H. K. Lewis.

of trichophytic invasion. The ordinary practitioner of or trionophytic invarion. The ordinary production of medicine will be inclined to agree with his view on the medicenses of "over-refining" in etiology, and of transcendental classification, for, after all, as in the present cendental classification, for, after all, as in the present volume, there is no correspondingly new or startling advance to be recorded in the treatment of the troublesome and refractory disease under notice.

As the result of a wide experience, Mr. Morris answers the question as to when ringworm of the scalp can be said to be cured in the following way:—"My own rule is, after a careful examination, to leave the case untreated for a month; and if no short hairs can be found, if the part is free from scaliness, and the new hair sufficiently grown to cover the patch, I pronounce the case oured." A chapter at the end of the book is devoted to the highly important point of prophylaxis, and some practical recommendations are made as regards elemen-tary schools. The main principles laid down are the need of systematic inspection, and of isolation without interference with education, as a matter of fact, precisely on the lines now adopted in dealing with ophthalmia in the Metropolitan Poor Law schools. The book is illustrated with over a score of artistic micro-photographic reproductions, and is exceedingly well published and edited.

British Medical Benevolent Fund.

THE annual general meeting of the above Fund was held on Friday, January 13th, at the residence of the Treasurer, Sir W. H. Broadbent, who occupied the chair in the unavoidable absence of Sir James Paget, Bart., the President. Dr. Samuel West, the Honorary Secretary for finance, presented the report of the committee and the financial statement for the past year. These showed that subscriptions amounting to £1,192 8s. 6d., and donations amounting to £492 7s. 11d. had been received and distributed in grants varying from £5 to £18 to 158 out of 184 applicants. Interest on invested capital had yielded £2,328 14s. 10d. from which annuities of £20 each had been paid to 108 recipients of theage of 60 and upwards. One new annuity had been created, and twelve annuitants elected during the year. The resignation, on account of continued ill-health, of Mr. Joseph White, the honorary secretary for cases, was received with great regret, and he was unanimously elected a vice-president, Mr. W. E. Sargant being appointed his successor. Cordial votes of thanks were passed to all the officers of the Fund and to the Press, both lay and medical, the meeting being concluded by a special vote of thanks to Sir William Broadbent, who for many years has taken as treasurer a great and active interest in the affairs of the charity. Although the above figures show an increase upon the previous year's receipts the grant department is still a to be passed over. The income of this branch is derived entirely from annual subscriptions and donations, and entrely from annual subscriptions and donations, and the committee earnestly appeals to the profession and others to become annual subscribers. A donation of £5, or a yearly subscription 10s., entitles the donor to the privilege of recommending cases. The books and accounts have been, as usual, exhaustively audited by a chartered accountant, Mr. B. F. Voelckher, who continues to act as honorary auditor of the fund, and who draws special attention in his report to the extremely small working expenses, which are again, as they have now been for some years, under 5 per cent. of the receipts,

The "Barker" Anatomical Prizes.

THE value of the prize is £21, and it is open for competition to any student whose name is on the Anatomical Class List of any school in the United Kingdom. The Class List of any school in the United Kingdom. The subject of this prize for 1899 has been announced by the Irish College of Surgeons as dissections to illustrate the anatomy of the larynx. 1. The preparation must be marked with a fictitious signature, and accompanied by a sealed envelope bearing outside the same signature. The competitor must make a declaration that the work has been carried out by himself. The printed form necessary for this declaration can be obtained on appli-cation to the curator. 2. The dissections are to be mounted in vessels fitted with glass covers. 3. No prize will be awarded unless sufficient merit he shown, 70 per cent. of the total marks being the minimum. The fol-

lowing is the scale of marks:—(a) For the merit of dissection, 60; (b) for excellence of setting, 20; (c) for originality, 20: total, 100. Those dissections become the property of the College 4. Those competitors who enter dissections for which prizes are not awarded, but which show sufficient merit, may be refunded such amount of the coat of production as the examiners deem fit. 5. The cost and risks of transport must be borne by the The prize is awarded by the curator of the stndent Royal College of Surgeons in Ireland, the President of the College, and the Professor of Anatomy of the University of Dublin

Bacteriological Department of King's College, London.

THE Secretary of State for the Colonies has intimated to the Council of King's College that, in selecting candidates for the Colonial Medical Services, preference will be given (other things being equal) to qualified medical men who have received such bacteriological or similar special training as King's College provides. Mr. Cham-berlain has conveyed his thanks to the Principal and Professor Crookshank for the assistance they have given in promoting the scheme for instructing colonial candidates in tropical diseases, and the Council of King's College and Professor Crookshank have promised to cooperate to the best of their power in carrying out Mr. Chamberlain's scheme.

Bradford and District Medico-Ethical Society.

Bradford and District Medico-Ethical Society.

THE annual general meeting of this Society was held on Wednesday evening, January 18th inst., at the Midland Hotel, Bradford. There was a large attendance, the following gentlemen being present:—Drs. C. F. M. Althorp, S. Johnston, J. Mossop, E. G. Peck, R. Hamilton, P. E. Miall, Bell Graham, W. A. Evans, T. Curtis Denby, W. Horrocks, J. H. Bell, F. W. Eurich, D. Goyder, W. Parkinson, Ar. Manknell, F. K. March, H. J. Butler, R. Love, Basil Hall, A. Rabagliati, A. Bronner, G. H. Moorhead, and W. Handcock.

The usual business of the Society was transacted and

Miall, Esq.; vice-president, Dr. T. Curtis Denby; treasurer, Dr. F. K. March; secretaries, Mr. W. Horrocks, Mr. Ar. Manknell. Committee, Drs. C. F. M. Althorp, D. Goyder, J. H. Bell, J. Mossop, A. Rabaghati, H. J. Butler. Auditors, Drs. W. J. Parkinson, and E. G. Peck.

Tuberculosis in Milk.

THE question of the sale of milk infected with tuber-culous disease has recently been under the consideration of a committee of the Westminster Vestry. The committee, having taken the opinion of the medical officer of health on the subject, will bring up a report at a meeting of the vestry on Wednesday, recommending that, in the interests of the public health, and with a view to preventing the spread of tuberculous diseases among children, a communication be addressed to the Local Government Board pointing out the need for legis-lation dealing with the sale of milk contaminated with tubercle bacilli; also that it be suggested to the other local authorities in the metropolis that their co-operation in the matter would be to the advantage of the public health.

Death from Tetanus.

An inquest was held on Saturday at St. Pancras, on the body of a man, aged 26, an ostler, who on January 12th was passing through Russell Square when the gale was at its height. His hat was blown off into the garden of the square. He thereupon mounted the rails, and a spike ran through an old shoe, penetrating the foot. He subsequently attended the Royal Free Hospital for treatment, and was admitted on January 17th. He died there last Thursday from tetanus, a result of his injuries. A verdict of "Accidental death" was returned.

A special General Board of Governors of the St. John's Hospital for Diseases of the Skin was held at the Westminster Palace Hotel last week, on requisition, to consider the action of the Board of Management with regard to a letter addressed by them to Dr. J. Vinrace, dismissing him as physician of the Hospital There was a large attendance, and after an animated discussion the action of the Board was endorsed by the Governors, the voting being thirty-eight for and six against.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be mared by attention to this rule.

BUROPHEN AS A SUBSTITUTE FOR IODOFORM. To the Editor of the MEDICAL PRESS AND CIRCULAR.

To the Editor of the MEDICAL PEESS AND CIRCULAR.

SIR,—I had recently under my care a patient suffering from extensive cancerous mischief of the left breast. The bre-st had been removed some twelve months previously, but the mischief returned and involved the surrounding tissues. There was a large foul smelling wound extending from the left axilla to the right of the middle line of the sternum, and about six inches long from above downwards.

The patient could not bear the putrid smell of this terrible mass, but said that, though so very bad, it was preferable to the pungent smell of icodorum which seemed also to interfere with her breathing, which was already much impeded. All wet disinfectants as carbolic acid, liq. hydrarg., perchior, sanitas, &c., seemed to make the wound worse, and could only be used for cleaning night and morning. There was a distinct odour about the room, and even the house. On my using europhen the smell was quickly kept under, and after a few days the house and room had no taint in it. I can only add that europhen did all that is claimed for it, and rendered the remaining weeks of my patient's life bearable. life bearable.

I am, Sir, yours truly,

A FAIR STUDENT'S DIFFICULTY.

A FAIR STUDENT'S DIFFICULTY.

At a clinique some time ago a genial physician had occasion to draw the attention of his class to a certain symptom commonly associated with the disease he was demonstrating. The class consisted of ladies, and one was asked to come forward and mark the symptom. This consisted of a specific sound heard in the neck region, and which proceeds from an arterial source; it is technically known as the "brut de diable." The fair student expressed herself unsatisfied; it had not appealed to her as being obvious at all, and certainly the sound belied its name. "Ah! I see," said the physician, smiling, "you have misinterpreted the French term. 'Brutt de diable' does Not mean a 'devil of a noise."—

Original Communications.

TWO RECENT CASES OF SUCCESSFUL OPERATION FOR IMPACTED STONE IN THE URETER, (a)

By P. J. FREYER, M.A., M.D., M Ch., Surgeon to St. Peter's Hospital.

The short paper to which I invite your attention this evening is to be regarded as a mere fragment—a brief contribution to the surgery of the ureter. This latter is a subject which during the last few years has engaged the attention of surgeons; and, still, how few instances of operation for stone in the ureter have been placed upon record. I think you will agree with me that it is incumbent on every surgeon who meets with such cases in his practice to publish details thereof, so that, in time, we may have accumulated a sufficiently large and varied number, as a basis from which to draw authoritative conclusions as to the best methods of dealing with stone impacted in any particular part of the ureteral canal. It is in this spirit that I venture to place before you details of two cases of operation for impacted ureteral calculus which have recently fallen to my lot, each in its way, I venture to think, possessing some features of interest.

Lieut. D., Royal Artillery, et. 23, sent by Dr. Blood, of Woolwich, consulted me on July 19th, 1898. He had suffered, off and on, for 19 months from renal colic and hæmaturia. The symptoms first set in at Malta in January, 1897, in the form of coliky pains in both loins, extending across the abdomen, whenever he rode on horseback. These were at first considered to be due to indigestion; but on the third or fourth day on dismounting he found that his urine contained blood, so he went on the sick list. The symptoms passed off in a few days with rest and treatment. Three weeks later, his duties being heavy and involving much riding, the symptoms returned, and he had again to go on the sick list. The pain at this period was mainly confined to the left side, commencing in the loin, shooting down to the groin, and sometimes across the abdomen, giving rise to the sensation of a string being tied tightly round the body. At no period did the pain shoot down into the testicles, nor was the organ retracted

The symptoms continuing, he came to England in May, 1897, and placed himself under the care of a well-known London physician. The renal attacks with hæmaturia continued to come on periodically every fortnight or so, and, strange to say, two of his worst attacks seemed to have been brought on by short sailing trips, though he did not suffer from seasickness. Getting no better he returned to Malta in August, 1897, and during the voyage painless hæmaturia set in, which continued, off and on, till September, when another severe attack of pain in the left

lHe was then seen by Major Swabey, R.A.M.C., the case as one of stone Unable to continue at duty who diagnosed in the kidney. he went to Sicily, but the voyage again brought on hematuris, accompanied by fever, which after lasting a week again wound up with severe colic. He returned to duty at Malta at the end of the month of October, but had to lie down for several hours in the middle of the day to relieve the pain. The re-drilling commenced on November 1st, and the first routemarch brought on pain and hæmorrhage. He was excused marching and rode in a carriage, but though the pain was less the hæmorrhage continued. December he passed two stones by the urethra, cylindrical in shape and like red sand-stone. The acute pain up to this was in the left side; and from that period till July, 1898, though there was occa-sional hæmaturia and the urine contained albumen, there was no severe pain, merely a dull aching in

oin occurred, and the hæmaturia suddenly ceased.

In May, 1898, he returned to England for duty at Woolwich. On July 10th he took a lot of exercise, and next day an acute attack of pain set in in the right side, which lasted seventy-two hours continuously, during which he was kept under the influence of morphia by Dr. Blood. The pain was excruciating, accompanied by restlessness, nausea, and vomiting, with constant desire to micturate, only a small quantity of high-coloured urine passing each time. For two days after this attack the urine was clear, but atter that became thick and bloody again.

I found that there was a slightly movable tumour in the region of the right kidney as large as two fists, extremely tender on palpation both in the loin and in front. There was no stabbing pain on pressure at the back, but distinct tenderness at one spot in front, midway between the navel and the anterior superior spine of the ilium. Urine, colour of Madeira wine, acid, sp. gr. 1015, containing blood corpuscles and crystals of oxalate of lime, also albumen. The left kidney was normal. My diagnosis was—stone in the pelvis of the kidney, trying to pass down the ureter and causing obstruction of urine.

On July 30th the patient entered a surgical home, and on August 1st I operated, Mr. W. Braine giving the anæsthetic and Mr. B. Smeaton assisting. Drs. A. M. MacDonnell and H. T. Griffiths were also present. The kidney was rapidly exposed through an oblique lumbar incision 4½ inches long, and the fatty capsule opened. No stone was detected on feeling it all over. The kidney, which was much enlarged and congested, was stripped of its fatty capsule and brought out on to the loin through the wound. I felt it carefully all over, but could detect no stone. The kidney was then opened through the convex border by means of a scalpel, and my finger passed into the pelvis, a rush of urine taking place through the wound, and the kidney collapsing much in size. No stone could be found, though my finger passed easily into the calyces, which, with the pelvis, formed a large, smooth-walled cavity. I then passed a catheter down the ureter as far as four inches from the pelvis, where it was obstructed. A long silver probe

₹(a) Paper read before the Medical Society of London, January 23rd, 1899.

was then passed, and a stone felt in the ureter at this

point.

The incision in the loin was at once extended downwards and inwards for four or five inches, and the peritoneum raised inwards from off the ureter by my fingers, till I could grasp the stone (which felt the ingers, till I could grasp the stone (which left the size of a filbert), lying in the ureter between my finger and thumb. I made several attempts to push the stone upwards into the kidney, but it was too firmly impacted in the ureter, so the ureter was incised longitudinally over the stone, which was pushed through the wound by the point of my finger. A bougie was then passed into the bladder through the ureter from the palvie. I did not suture through the ureter from the pelvis. I did not suture the wound in the ureter because (1) suturing of the ureter when a stone is removed extra peritoneally is a debatable proceeding; (2) the ureter was so narrow that suturing would probably cause contraction of the canal; and (3) though I could extract the stone with the limited incision already indicated, the successful suturing of the ureter at the bottom of a deep wound was impossible without a much more extended dissection. I contended myself, therefore, by placing a large drainage tube down to the opening in the ureter, along the back of the kidney, bringing the muscles together by buried silk sutures, and the superficial parts by silk-worm gut. The wound in the kidney was partially closed by two sutures, the middle portion being left open so that the urine might flow freely through the loin, and thus avoid tension on the ureter till the wound in it should have healed.

Bloody urine was passed freely by the urethra in the evening, showing that the ureter was patent; and bloody urine by both loin and urethra for several days. On the third day I began to shorten the drainage tube daily, and this was completely removed on August 7th. On the 8th the wound was firmly united, save in the track of the drainage tube. On the 9th

urine ceased to flow by the loin.

The patient made a rapid recovery; was sitting up on August 28th; went for a walk on September 2nd; and left the home on September 7th, travelling by train to Margate. Soon after he began to bicycle; he started to rejoin his battery at Gibraltar on November 15th. He is now in excellent health, and wrote to me in the end of December last that he does five or six hours work daily with his battery, ascend-

ing the Rock 1,300 feet.

It may be of interest to mention, as bearing on the hereditary tendency of stone, that owing to the successful result in this case, the patient's mother, who for seventeen years had suffered from stone in the kidney, placed herself in my hands. On September 28th, 1898, I performed a lumbar nephro-lithotomy. Dr. Dudley Buxton, anæsthetist, and Mr. Swinford Edwards assisting me, removing one largish oxalate of lime stone from the pelvis, and several smaller ones from the calyces. The kidney, which was extremely large, was sutured. No urine passed by the wound, and the patient made a rapid and successful recovery. Furthermore, this lady's father suffered severely from gravel for many years before his death. Some years ago I operated successfully for stone in the bladder on three generations in the same year—son, father, and grandfather.

The second case, a man, æt. 53, has been a patient at St. Peter's Hospital, off and on, for thirteen years, suffering from multiple stricture of the urethra, which has been operated on several times. and symptoms of kidney stone. In 1895 his left kidney was explored for stone by another surgeon, but with a negative result. Temporary relief ensued, but the old symptoms again returned, and in the summer of 1897 he was very ill, the pain in the left loin being very severe at times, radiating to the groin and testicle, and accompanied by hæmaturia, which at times was very profuse; there was also occasionally pain in the

right loin. The urine was extremely thick and offensive, and on standing deposited pus amounting to half its bulk. I determined under these circumstances to explore the left kidney again, which was accomplished on September 1st, 1897, by an oblique lumbar incision. A most careful search was made, but no kidney was found, though I passed my fingers well up under the ribs, down to the iliac fossa, and inwards to the aorta, pushing the peritoneum out of the way. The patient rapidly recovered from the operation, but there was only a very temporary relief to the symptoms, which soon set in as bad as Under the impression that the symptoms might in large part be due to backward pressure, resulting from the stricture, which had again contracted, so that a No. 6 bougie, English scale, was passed with difficulty, I performed internal urethrotomy on November 18th, 1897, cutting three dense cartilaginous strictures up to 16 of the English scale. The patient was extremely ill after the operation for two days with severe rigors, the temperature rising to 106 degs. F., and the urine being very scanty; but he recovered, though slowly, leaving the hospital early in January. This operation, though it afforded a free flow for the passage of his urine, did not much diminish his other symptoms. Though the pain in the left loin gradually diminished, that in the right loin increased, and for months he continued to attend the out-patient department, his urine constantly containing much pus, and at times a considerable quantity of blood. Occasionally the right loin became much swollen, and the disappearance of the swelling was always followed by an increase in the quantity of pus in the urine. In October, 1898, he began to complain of great irritability of the bladder; there was constant desire to pass water with pain at the end of the penis. He was admitted into hospital, and on November 9th I cystoscoped him under an anæsthetic, and detected a long, narrow, rough, pencil-shaped stone projecting into the bladder from the right ureteral opening. The portion of stone projecting into the bladder appeared by the cystoscope to be about ? in. long, and dark grey in colour. My colleague, Mr. Reginald Harrison, and others had an excellent view of the stone. I at once introduced a lithotrite, and after three or four unsuccessful attempts, eventually caught the stone between the blades, pulled it out of the ureteral opening, crushed it and removed the debris by the aspirator. The debris consisted of urates and weighed 12 grains. On November 23rd the patient was again cystoscoped. The bladder walls were coated with mucus; both ureters were seen to be acting, and flakes of pus were seen issuing from them.

The patient has continued to improve steadily in health. The pains in the loins have disappeared; there is no hæmaturia and scarcely any pus in his urine. He states that he is in better health than he has been for years.

The history of this case presents many points for speculation which would, however, be foreign to the purpose of this paper; the case being now brought forward only for the purpose of illustrating what I believe to be a novel method by which a stone projecting into the bladder from the ureter may possibly sometimes be successfully removed.

I will, in conclusion, briefly refer to five other instances of stone impacted or encysted in the ureter, which have been operated on by me—four of these during my experience in India. In three, the stone was impacted at the ureteral orifice, projecting into the bladder and felt by the sound. One occurred in a female, two in males. In each instance an operation was undertaken, under the impression that I had to deal with an ordinary case of stone in the bladder and in each case the stone was dislodged from its

position by introducing the forefinger through the dilated urethra in the female and through the ordinary perineal lithotomy wound in the males, scraping the orifice of the ureter by the finger nail, the stone being forced downwards and inwards by the hand placed on the groin, and then r. moved by the ordinary

lithotomy forceps.

In the British Medical Journal, May 9th, 1891, page 1,005, I have given details of a boy, æt. 15, from whom I removed, at two different sittings, by litholopaxy two separate stones, weighing respectively 757 and 581 grains, aggregating more than 3† ounces After removing the first stone from the bladder, I found that there was a second lying in the lower part of the right ureter close to the bladder. The second stone was felt as a hard tumour in the loin, about 3 inches long, and could easily be felt in the ureter between a finger in the rectum and the hand on the groin. I determined to remove this stone by suprapubic cystotomy as soon as the patient should have recovered from the first operation, but on the fourth day the tumour in the groin suddenly disappeared, and a stone was felt lying free in the bladder, and successfully removed by litholopaxy. Evidently this latter stone. lying in the ureter, rested on the stone located in the bladder; as soon as this support was removed the ureteral calculus was pushed into the bladder by the force of the accumulated urine behind it.

The fifth case is recorded in the "Medico-Chirurgical Transactions," vol. 81. It was that of an obscure cystic tumour of the bladder, which contained two calculi, weighing 41 grains, removed supra pubically. My explanation of the case was this—that the stones descending from the kidney were arrested at that portion of the ureter which passes obliquely through the bladder wall, and that, unable to escape owing to a contracted orifice, they bulged the bladder wall inwards, forming a smooth cystic tumour which was recognised by the cystoscope, and successfully dealt

with in the way indicated.

Harley Street, W.

THE ELECTROTHERAPY OF INFLAMMATORY AFFECTIONS OF THE EYE.

By PERCY DUNN, F.R.C.S., Ophthalmic Surgeon to the West London Hospital.

THE eye is obviously, for anatomical reasons, an inconvenient organ for the efficient application of electricity. For the most part, therefore, the study of the subject of electro-therapeutics has never found much favour among ophthalmic surgeons. America, however, a good deal of importance appears to be attached to the electrical treatment of eye diseases. On the other hand, in this country it is doubtful whether any ophthalmic surgeon regularly resorts to, or even recommends it. The object, nevertheless, of this paper is to draw attention to some recently published observations upon the subject by Reuss of Vienna, which are not without interest. The originality, perhaps, in Reuss's observations rests in the fact that they are confined to inflummatory affections of the eye, and that he claims for the faradaic current a superiority over the galvanic current in the treatment of these cases. In 1896 he published the results of his ten years' experience of this method of treatment, and in Graefe's Archiv. f. ophthalmol. for September 2nd, 1898, some further results appear, giving his most recent views as to the value and suitability of electro-therapics in inflammatory ocular affections So far as the galvanic current is concerned his objections to it are: (1) So far as the galvanic

That a galvanometer is required; (2) that the current can only be applied by a medical man; (3) that excoriations may be caused; (4) that harm results if a current of too high a power be used.

Reuss, therefore, enjoins that the faradaic current should be employed in all cases, save those of scleritis. With regard to the latter he recommends the gal-vanic current, as being more active and more useful than the faradaic current.

The following is the method described as the best for applying faradaism to the eye. A small metallic electrode is used, made in the form of an oval cup 40 mm. by 28 mm. in size. Between the electrode and the closed eye a layer of moist cotton wool is placed, while the other electrode is held by the patient in one of his hands. The intensity of the current is regulated by the patient's tolerance of the sensations produced. Séances lasting from fifteen to thirty minutes are recommended But in exceptional cases these may te prolonged, even to an hour. Mention may now be made of the particular diseases for which Reuss has

successfully employed electricity.

In iritis and iridocyclitis he affirms that the treatment is strikingly beneficial in causing the relief of pain. The pain disappears as if by magic. "In order," he says, "to convince my class of this fact, I showed a patient suffering from an acute attack of iritis, accompanied by intense pain and blepharospasm. I applied faradaism there and then; and in the course of a minute and a half or so, the pain was relieved, and the patient opened his eye and gazed wonderingiy round the class." However, he admits that the relief is only temporary, that is to say, the pain recurs if the current be not soon re-applied. According to Reuss the duration of the relief varies with the period during which the faradaism is employed, and he thinks that the latter should be applied for at least half an hour in bad cases.

In this connection reference may be made to the experience of Alleman, of Brooklyn. holds that in cases of acute iritis the use of electricity is of doubtful benefit. In some cases he has seen the pain relieved by the application of the anode to the closed lids with a current of one milliampère for two or three minutes, but, he adds, "this will often prove of no avail." The difference, however, in these results may be due to the fact that while Alleman uses a galvanic current, Reuss uses a faradaic one.

One of the advantages claimed for the use of electricity in these cases is that it facilitates the absorption of iritic exudations, and upon this point there seems to be a concurrence of opinion among authorities. Alleman, for example, states that he has had the most satisfactory results from the use of the galvanic current in cases of adhesions and inflammatory deposits following iritis. He has found that the adhesions have given way, and that a manifest improvement in the vision has resulted. The most effective mode of application is to place the cathode with a current say, of two milliampères, upon the closed lids for five minutes

Reuss recommends faradisation for fifteen to thirty minutes in keratitis; he states that the photophobia and pain are marvellously relieved by this means, even before any other treatment has been employed. He further adds that faradaism may be employed to relieve the pain and photophobia in phlyctenular conjunctivitis. The application, however, of electricity for the relief of photophobia is not new. Many observers have alluded to the utility of this form of treatment, and among others Benson, of Dublin, has recorded thirty-two cases in which its value was markedly demonstrated.

It would be interesting to test the value of a faradaic current upon a chronic vascular ulcer of the cornea. Such ulcers are known in some cases to prove extremely rebellious to treatment. I have elsewhere pointed out the treatment for these, which, in my hands, has proved most successful. (a) But every therapeutic measure may fail, as occurred in a case of a schoolboy, et. 14, who was lately under my care.

Master A. was brought to me by his father in June last, with a small ulcer upon the lower part of each cornea. My usual treatment was prescribed, and for a time the result was quite satisfactory. But shortly after he returned to school the ulcers relapsed. I therefore urged the necessity of sea air to complete the cure. The boy was sent to Herne Bay, and after having been there for six weeks, he came back to town greatly improved in health, with one eye quite sound and the other (left) practically well. Within, however, a fortnight's time the left eye again became deeply injected and painful, and the ulcer again resisted treatment. As it was useless for the boy to attempt to resume his school work, I advised his father to send him for a further term to the seaside. My patient, therefore, was sent to Broadstairs for nine weeks, and I recently saw him on his return. He is now in every way fully restored to health, both eyes being quite sound. It would have been interesting in this case to have tried the effect of faradaism upon the intractable vascular ulcer of the left cornea. Local treatment, however, must be futile, unless and until the constitutional vice has been removed upon which the malnutition and the ulceration of the cornea depends.

Another class of cases in which Reuss affirms that he has employed electricity with benefit is that of inflammatory conditions of lost eyes, and he claims as the result thereof that he has been able to avert the necessity of surgical interference. But this must surely be a doubtful advantage. An inflamed and lost eye which is painful should be removed, and especially is this the case if the fellow eye be sound. Nothing is to be gained by retaining a lost eye under such circumstances, while the risk of sympathetic ophthalmia being excited by the useless organ can scarcely be overlooked, despite the fact that such an untoward contingency would not accord, perhaps, with the modern views of the micro-organic origin of

his fatal ocular affection.

Upon the subject of the use of electricity in the treatment of vitreous opacities Reuss expresses himself somewhat guardedly. "The same can be said," he asserts, "of electrical treatment in these cases as can be said of other forms of treatment: in a certain number of patients the results are successful, with in others there is failure." He believes, however, that electricity is an excellent adjuvant to other remedial measures. Incontradistinction to these remarks reference may be made to the published experierce of American and other authorities. Girard-Teulon states that the electrical current is the most effectual and also the most rapid remedy in the treatment of vitreous opacities, and Alleman also affirms that the current has been employed with much success in these cases. Again, Little (Philadelphia) has recorded in the Transactions of the American Ophthalmological Society several cases in which the electrical treatment was beneficial, and he believed it to be of Similar results have use in any form of hyalitis. been recorded by Le Fort.

In the treatment of intra-ocular hemorrhage Reuss states that blood in the anterior chamber is quickly absorbed under the influence of a faradaic current, but he definitely admits that electricity is of no use in cases of retiral hemorrhage. Upon this point he and Alleman are again at variance. The latter expresses himself as follows:—"In hemorrhagic retinitis the palvanic current may be employed with the reasonable expectation of clearing up the hemorrhages, and of preventing recurrences. In diabetic

retinitis, with or without a central scotoma, the treatment is especially indicated."

The tragic accident which occurred to Duchenne, by which the sight was destroyed in a patient to whose eyes he applied electricity, was sufficient for some time to throw this method of treatment into the shade. But even apart from any consideration of this kind there does not appear to be much field for the useful application of electricity in the treatment of ocular affections. Nevertheless, I thought that it would be of interest to call attention to some of the latest views expressed upon the subject, and thus this paper has been compiled.

Paris Clinical Lectures.

THE TREATMENT OF ACUTE INTESTINAL OBSTRUCTION.

Delivered at the Hôpital de la Pitié, Paris.

By PROFESSOR P. BERGER, Professor of Clinical Surgery.

Among the problems which present themselves in clinical surgery there are some, the solution of which needs establishing in advance. These are cases where the necessity for prompt resolution leaves no time for prolonged study, and in which it is necessary to act according to rules already laid down. In no department of practice are such rules more de-manded than in presence of acute obstruction of the bowels. In cases such as hernial strangulation it is upon rapid action that success depends; but here ends analogy between the two conditions, in spite of the similarity of their symptoms. Cases of strangulated hernia can receive nothing but advantage from operative interference, and the operation ought to be performed not only in the most numerous cases in which diagnosis demands it, but even in doubtful cases, since the operation is simple, easily performed, rapid, and absolutely devoid of danger, and certainly efficacious in every instance in which it is resorted to in time.

Very different is the solution in presence of a rapidly progressing case of internal strangulation. The chances of recovery, even in the absence of all operative interference, always exist; and operative intervention itself always seriously presents to the surgeon two different courses, of which each belongs to a certain class of case, and is useless or even hurtful in others. These procedures are laparotomy and enterotomy—to use terms as classical as they are in appropriate—by which are designated two operations, between which there has been established a distinction which exists only because we are too often incapable of recognising the cases which one or the other ought to be reserved for. Before considering these indications, let us first strive to balance them to explain their advantages and their dangers. The surgeon, in presence of an intestinal obstruction, ought to go straight for the obstacle. To recognise and do away with this, such is the end to which laparotomy leads—the abdominal incision, which is itself merely a means of access, and to which has nevertheless been given the name of the method of intervention itself. This is the only rational operation and the only one capable of yielding complete success from the surgical and practical aspect of the case. It is to this that the most brilliant successes are due: the immediate termination of all complications and a rapid cure in cases apparently desperate; but this operation is dangerous, and often inefficacious.

Operative statistics bring out the enormous mortality which follows the procedure: 102 cures, 226

deaths, 69 per cent. of failures in Farquhard Curtis's hands, 25 deaths—that is, 60.5 per cent. mortality in the practice of Obalinski; and we have lately heard our colleague, M. Schwartz, at the last meeting of the Société de Chirurgie, state that there were only two cures in seven cases in his wards at the Cochin Hospital. Only a little less unfavourable were the results communicated to the Congress of German surgeons by Z. Heidenhain. Out of 30 laparotomy operations for acute intestinal obstruction performed in the clinic of Prof. Helferich 14 only were cured. At the Société de Chirurgie this year also M.M. Hartmann and A. Broca brought forward facts in sufficient numbers giving a proportion of 45 to 50 per 100 recoveries from laparotomy. In spite of these scarcely less discouraging statistics, the proportion of failures which follow laparotomy remains very considerable. In appreciating these, though it is necessary to bear in mind the gravity of the patient's condition and his exhaustion at the time of operation, and to make these responsible within certain limits for the drawbacks attending the opera-tion, one ought not to forget that the operation must in a good number of cases tend to precipitate a fatal termination. This it may do by its long duration, by the intra-abdominal manipulations which it necessitates which aggravate the collapse resulting from nervous shock and exposure to the atmosphere of a large portion of the surface of the bowels -an exposure which it is not always possible to prevent in searching for the seat of strangulation. The operation is often ineffectual. Too frequently it merely establishes the eact that the obstruction cannot be removed, or at any rate not without performance of an operation so prolonged and laborious, as to be out of the question in the precarious condition of the patient. Of this, examples will be presently given. It even happens that minute search fails to discover the obstruction or demonstrates that no material obstruction really exists. In all such cases establishment of an artificial anus is the sole resource; but this is accomplished when the patient, often exhausted by the prolonged operative procedures, has lost the favourable chances which a more rapid selection of operation might have preserved for him.

Nélaton's operation, enterotomy, the immediate establishment of artificial anus, does not present itself under a more favourable aspect. Statistics show a mortality following this operation almost as great as that after laparotomy. And it must be noted that laparotomy is rarely practised except in favourable cases, cases in which the powers of the patient are not exhausted, whereas artificial anus offers a chance of relief which ought not to be withheld from the parient even in the most critical situation. Statistics of this operation give a great number of instances in which an unfavourable ending has been due to the disease itself and not to the operation.

Practised under ordinary conditions establishment of an artificial anus is a rapid and simple operation, which may often be carried out even without ansesthesia. It gives immediate relief, even if it does not remove the obstacle to the passage of the contents of the bowels. The rapid emptying of the intestines and subsidence of inflation of the belly often after a few days enables discovery of the cause of obstruction to be made, and creates more favourable conditions for a new operation. In certain cases the complete emptying of the higher end suffices to bring about in course of a few days spontaneous re-establishment of a normal passale with closure of the artificial opening soon after. A case of this kind I saw last year with M. Tapret and Nélaton. This was in a man, et. 40, who some months before had suffered attacks of acute occlusion which had yielded to medical treatment.

When I saw him nothing but gas had been passed per anum for three days; the belly was so distended that the abdominal walls seemed ready to burst; the distension was mainly towards the right side, where also colon was most localised, and palpation revealed the greatest tenderness.

An operation was decided upon. I made along the external border of the right rectus, an incision permitting admission of my hand. I found the cæcum, the ascending colon, and the transverse colon enormously distended, the cæcum having at least the dimensions of an arm. The distension ceased suddenly in the left hypochondrium, and I examined the junction of the descending and transverse colon without discovering any stricture or material obstacle at that point. Fearing to compromise favourable chances by prolonged incisions and examinations, and taking great pains to maintain the bowel which tended to protrude, I resolved to form an artificial anus in the cæcum. I closed the incision throughout the greater part, fixed the cacum at its lower angle, and opened it by an incision one centimetre and a half long. An abundant discharge of gas and of liquid matter occurred through this opening, and at the end of eight days the obstruction, whatever it may have been, had disappeared, and two months later the opening of the intestine in the abdominal wall had closed without operative interference. I saw this case within the last few days. The patient has had no further trouble for a year and a half.

The establishment of an artificial anus thus gives immediate relief, averts the more urgent complications, and makes life secure for a time, and sometimes makes possible a complete cure with or without further operation. It is not necessary to dwell upon the horrible and often permanent infirmity at the price of which these advantages are obtained. On the other hand, there are many cases in which artificial anus does no good; others in which it is hurtful If the obstacle is situated in the small intestine at a point at a spot above the ileo-caecal valve the artificial opening above the point will have the effect of suppressing the intestinal functions in the whole length of bowel below. Thus if the clinical facts brought forward by Trzebichy, and others prove that the function of the bowels may be suppressed without serious consequences up to 2 m. 80 of the length of the small intestine it is none the less certain that an artificial anus placed too high exposes the patient to rapid malnutrition and death within a s ort period. There are, moreover, cases of occlusion in which opening the bowel does not prevent a case taking a fatal course.

Last year an elderly female was admitted to my clinic presenting all the symptoms of acute intestinal occlusion lasting at least three days. She was already very weak, the pulse was rapid and small, expression much changed, anxiety extreme, the belly distended and painful, especially on the left side. After examining for hernia and finding none I considered that artificial anus gave the patient the best chance of recovery. M. Reblant performed the operation with great rapidity, but no improvement followed, and the patient died within 24 hours. The autopsy disclosed a strangulated obturator hernia. Perhaps a more minute analysis of the clinical facts would have led to recognition of the real condition. The patient had complained of a pain in the thigh, and this ought to recall the fact that it is not only the orifices which give passage to common herniae which ought to be examined in acute occlusion, but also the orifices of exceptional herniæ. I shall return presently to this point.

I had thus committed a fault of observation; and if the majority of surgeons, who have had cases of a similar kind, have in like manner erred, since only 57 cases out of 135 of this character were correctly diagnosed, this does not diminish my error. But even admitting that the hernia could not have been recognised before the operation, the choice of that operation was quite ill-advised; the artificial anus had not relieved the strangulation; laparotomy would have permitted its recognition. Would this have saved the patient? It is very doubtful, but it would have obviated the regret of having missed the true cause of the trouble. The result must be the same in a large number of the class of cases properly termed internal strangulation. In this variety, artificial anus, apart from the fact that it is most frequently established in the small intestine—that is, in too high a situation—does not stay the progress of the malady, since the constriction persists in spite of it.

The conclusion from what precedes is that it is necessary to recognise the nature and the situation of the obstacle to be dealt with. Laparotomy, which answers in some cases, is hurtful in others; artificial anus, which alone is applicable to these, is insufficient to prevent ill results, and is consequently useless under the circumstances in which laparotomy alone

is indicated.

As we have just seen, laparotomy is alone applicable in cases of true internal strangulation. It answers in strangulation by bands, by adhesions, and in diverticular strangulations. If the intestine is nipped in an abnormal orifice of the mesentery created by a prior operation, or by an epiploic cord wound round it, the course of the mischief cannot be stayed except by releasing the intestine from the constriction.

The same considerations apply even more forcibly to all cases of deep herniæ, of preperitoneal or retroperitoneal herniæ; and of internal herniæ. Belonging to this category is the hernia which occurs in the posterior cavity of the omentum through the hiatus of Winslow, the hernia of Trentz, the hernia of Douglas's pouch, and the retrosessile hernia of which Samter has published an interesting example, and the deep strangulated laparoceles such as Ferrier and Furneaux Jordan have recognised and cured by laparotomy; certain obturator hernize of which we shall give an example, and the ischiatic herniæ (hernia ischiatica incipiens, Langer) consisting of a lateral compression of the intestine; certain inguinal herniæ; and especially cruro-peritoneal and even anomalous crural herniæ like the pectineal hernia of Alberti. In all these instances when there exist no external signs laparotomy alone can lead to recognition of the nature of the case, and of the seat of the obstruction; and if the r sults are often unsatisfactory it is mainly because delay has allowed grave injury to the bowel or hernial sac to supervene.

Amenable also and solely to laparotomy are cases of occlusion due to impaction of a biliary calculus in the bile duct or even in the small intestine -accidents often very difficult to account for but which can be dealt with only by extraction of the foreign body by laparotomy. To be logical we ought also to group here torsions of the bowel, cases of volvulu, of which the most frequent cause is intestinal or mesenteric adhesions, but which would maintain and render permanent the effects of plastic peritonitis around the twisted portion of intestine. Logically also it is laparotomy which should be preferred in cases of invagination, for this operation alone allows of recognition of the amount of ulceration or irreducibility of the intestine, the seat of intussusception. It is after having seen and made out the state of things that the reduction of the invaginated bowel may be attempted or resection of the irreducible knuckle of intestine, or that the question of artificial anus may be considered. But the results of operations, however rational these may appear, do not always answer expectations. It is in cases of invagination that laparotomy has been followed by the highest mortality; the statistics are hardly better in volvulus, and the enormous proportion of 80 per cent. mortality which accompanies these operations, shows that the most rational indications are not always those which succeed best.

There is another group of cases which it may seem strange to describe as acute occlusions, but in which the symptoms of strangulation advance rapidly and render them difficult to distinguish from actual internal strangulations. There are cases of compressions sion of the bowel by tumours; of stenosis; of cancerous narrowing and specially of these where the phenomena of occlusion appear suddenly. It has often happened to me to open the abdomen expecting to find a strangulation due to a band or some similar cause, and to come upon an annular cancer of the iliac flexure of the colon which had made itself known only by the crisis for which I was called upon to intervene. In these cases an artificial anus is the sole resource. Ablation of a tumour of the bowel and reestablishment of continuity by suture in an exhausted patient, and with the further local conditions involving enormous dilatation of the higher portion of bowel by gas and solid matter can hardly end otherwise than in failure.

In Heidenhain's statistics, just quoted, laparotomy for deeply placed narrowing of the bowel give six deaths in six cases. Creation of an exit for matters as quickly as possible is the only thing to be done in these cases; and here it is that artificial anus affords a remedy, provided it is established without delay. Later, when the first danger has passed away, when the bowels have resumed their normal dimensions, it may be possible to attack the seat of mischief, and to remove the tumour causing the pressure; enterectomy and enterorrhaphy being done under more favourable conditions. The actual indication, and the only one to attend to first, is to give free vent to the contents of the bowel.

Other cases, again, are met with in which the bowels are the seat of distension, for which no material cause can be discovered. I was called to a woman, 75 years old. She had been in perfect health up to four days earlier. Following a mild attack of indigestion, the belly became distended. There was colic, and frequent desire to evacuate the bowels, but neither gas nor solid matters escaped. Vomiting followed, and the pulse became weak and small. She seemed dying, and the pructitioner in charge of the case did not think her fit to bear the smallest operation. Mr. Paul Regnier, however, resolved to give the patient a chance by making an artificial anus; but an enema administered as a preliminary, joined to the effect of the emotion caused by the proposed operation, brought on an evacuation of old fectid contents of the bowels; and within a few days complete recovery took place. In this case obstruction by fæces had become in an aged, fee sle patient a cause of paralysis of the bowel which might have terminated fatally.

M. Sejars has recently communicated to the Société de Chirurgie five cases of the highest interest of patients attacked with symptoms of acute occlusion in whom laparotomy revealed enormous distension of the entire intestine without the existence of any appreciable obstacle. A small button-hole opening in the cæcum, by allowing evacuation of gas and solids, sufficed to cure these cases – examples of pseudo-strangulation without discoverable cause. In cases of this kind electrical treatment methodically applied, according to the method of M. Boudet, sometimes does wonders. When symptoms persist a small flap opening is the proper thing if the nature of the case can be made out.

Side by side with the cases of pseudo-paralytic

strangulation must be placed those of spasmodic The existence of such a cause is strangulation. doubted by some authorities, but seems placed beyond doubt by the observations of Helferich who, in the course of the operations of laparotomy for relief of acute occlusion was able to establish the existence of spasmodic narrowing of the intestine, and the absence of any other obstacle save functional spasm. cases of this kind it is hardly necessary to say that if medical treatment fail-opium is the drug indicatedopening of the bowel is the most suitable procedure.

(To be continued.)

RHEUMATIC TONSILLITIS. (a)

By Dr. BERTRAM ABRAHAMS.

THE material upon which this paper is based is mainly composed of cases of rheumatic tonsillitis observed by the author during the last three years. A large number of cases of chorea, rheumatism, and cardiac disease, both in adults and children, have been investigated and tabulated, and the resulting statistics compared with those of previous observers, in order to ascertain as accurately as possible the relation of the throat affection to the rheumatism. The bacteriology of many of the cases has also been studied with a view to obtaining some light upon the ætiology of the disease itself. The bulk of the work, in so far as it relates to children, was done in the outpatient department of the Evelina Hospital for Children. Dr. George Carpenter was kind enough to permit the use of the material, and also to allow the results to be compared with his own works for the last ten years. Details are given in the paper of a number of cases illustrating—
(1) The occurrence of endocarditis after non-scarlatinal tonsillitis without the intervention of arthritis or chorea; (2) tonsillitis immediately followed by a first attack of chorea; (3) repeated attacks of chorea, each preceded by tonsillitis; (4) the occurrence of sore throats at various points in the rheumatic series. Clinically, five varieties of rheumatic throat affection may be distinguished. (1) Faucial erythema, the pharyngeal inflammation described by Trousseau as ushering in an attack of acute rheumatism. (2) Follicular tonsillitis. (3) Quinsy. Between these latter no pathological distinction can be at present drawn, though it is notable that when a patient has repeated attacks, they are almost always solely of one kind or the other, an alternation being rarely observed. As is also the case with non-rheumatic forms, the follicular variety is commoner in children, the quinsy in adults. (4) The abortive form described by Singer (angine rhumatismale of French authors), in which the joint and muscle pains are vague, is not so frequent as he states. No case should be included under this head in which there is not adequate personal or family history of rheumatism. After making this observation a considerable number of instances remain, the most noteworthy point about which is their liability to die suddenly from cardiac failure. (5) Chronic rheumatic tonsillitis is described by Dr. Max Thorner; this affection is more probably gouty in nature. A statistical inquiry was made into consecutive cases of three distinct affections, namely, 248 of chorea, 43 of acquired heart disease in children unassociated with chorea, and 66 of rheu-matic fever in adults. Of the choreas in which a reliable history was obtainable, 53.4 per cent. had a family or personal one of sore throat. This history was not associated with any marked predisposition to either arthritis or heart disease. Of the cardiac cases 66 7 per cent. gave a history of throat affections. Among the adults 45.5 per cent had a definite throat history, 21.2 per cent had suffered from ulcerated throats within three weeks of the attack of acute rheumatism, and 47.2 per cent. showed faucial erythema within two days from its onset. In children, where the commencement is insidious, faucial erythema is extremely rare. On the other hand, a large proportion of them had follicular

(a) Abstract of paper read before the meeting of the Clinical Society of London, January 27th, 1899.

tonsillitis when first seen, several being brought up on its account and either revealing cardiac disease when examined or developing chorea while under observation. There seems little reason to doubt that in many of these cases the tonsils may have been the channel of infection; this is, of course, by no means invariably true, as the sore throat is often a late term in the rheumatic series. Bacteriological examination of the tonsils and their exudation in a large number of cases revealed the constant presence of strepto- and staphylococci, the former more frequently, but the latter oftener in pure culture. Similar organisms were found in the urine drawn from the bladder with all antiseptic precautions. Taking these results together with the discovery of the same microbes in the blood and affected joints in acute rheumatism by Sahli and others, the probability of the occurrence of infection through the tonsil becomes very strong. It is believed by many that the rheumatic patient is poisoned by the attenuated virus of a germ which when fully active leads to pyemia. The following conclusions are put forward:-1. The more common varieties of rheumatic sore throat fall into two main categories, faucial crythema and tonsillitis proper. 2. Faucial erythema is most common in adults, rheumatic tonsillitis in children, in whom it usually assumes the follicular type, quinsy being more frequent in older subjects. 3. Faucial erythema is an initial manifestation of acute rheumatism, tonsillitis may be the actual primary lesion. 4. Many cases are now definitely on record in which endocarditis has followed a non-scarlatinal tonsillitis unaccompanied by joint pains. In numerous other instances the tonsillitis has immediately preceded an attack of arthritis or of chorea. 5. The presence of the same micro-organisms in the tonsils, joints, blood, and urine is evidence in favour of the participation of pyogenic cocci in the ætiology of rheumatism.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON. MEETING HELD, FRIDAY, JANUARY 27TH, 1899.

Mr. LANGTON, President, in the Chair.

THREE CASES OF ABDOMINAL SECTION.

Mr. J. Hutchinson, jun, read notes of three cases in which he thought it necessary to perform abdominal section. In none of them was there any external wound. Case 1. A man, at. 32, was run over and subsequently became collapsed. Slight abdominal distension and much tenderness with dulness beyond the left linea semilunaris which shifted on change of position. On the following day the temperature had risen to 102, and the abdominal distension had increased. On opening the abdomen he found it full of blood, but in spite of careful search he could find no vessel requiring ligature. Great relief followed the removal of the blood, but some oozing occurred, subsequently, as evidenced by dulness in the flanks and the escape of blood into the dressings. He left the hospital a month later. He raised the question whether the presence of effused blood within the peritoneal cavity was likely to prove injurious, and he thought it was. Case 2. A single woman was brought to the hospital with symptoms pointing to intestinal obstruction. On opening the abdomen over two pints obstruction. On opening the abdomen over two pluts of clear, pale, yellow odourless fluid escaped. The intestines were slightly congested, the stomach dilated, the uterus enlarged as at the third month of pregnancy. He was at a loss to discover the nature of the fluid, and closed the wound. In spite of a passing improvement the patient aborted on the following and died congester. For moreon the shydomen. ing day, and died soon after. Post-mortem the abdomen again contained a large quantity of the same serous fluid, and the intestines showed signs of commencing peritonitis. Exactly in the middle line of the posterior surface of the bladder, one inch above the peritoneal reflexion, and therefore hidden from view, was a small round perforation 1/7 inch in diameter, through which

urine could readily be expressed. Bladder and urethra otherwise normal. If the nature of the fluid had even been suspected he thought it might have been possible to discover and repair the perforation. He surmised, under the circumstances, that the wound was caused by an unskilful attempt to procure abortion. From the history, it seemed likely that urine had been leaking into the peritoneum for at least four days. He discussed the effects of effused urine in the peritoneal cavity, and recalled that experiments on animals had shown that healthy urine may be injected into the abdomen without giving rise to much local reaction, that in moderate quantities it may be absorbed and the animal recover. Case 3. A woman, æt. 47, was admitted with the history that, previously in perfect health, while lifting a basket on the preceding day she had been seized with pain in the left side of the abdomen, followed by vomiting and some collapse. A smooth, movable tumour could be made out to the left of the middle line about the size of a feetal head. This was dull on percussion, but there was no dulness in the flanks. Nothing of interest was made out by vaginal examination. He diagnosed ovarian cyst, the seat of a twist or rupture. On opening the abdomen a quantity of characteristic glairy fluid escaped, and it was seen that the largest cyst of a multilocular ovarian tumour had ruptured. The fluid was sponged away, but the cavity was not irrigated. Recovery followed. Admitting that the thin serous fluid of an ordinary ovarian cyst might, if effused in the peritoneal cavity, undergo absorption without giving rise to much trouble, he asked whether this thick glairy fluid would prove equally innocuous.

The PRESIDENT, commenting on the first case, observed that though blood in the peritoneal cavity need not give rise to septic mischief it would, nevertheless, be advisable to operate, because one could not know the conditions which had given rise to the effusion. He related the case of a man who had received a bullet wound three inches below the nipple. As there was internal hæmorrhage he opened the abdomen and found that the liver had been extensively lacerated, but ultimately he managed to arrest the hæmorrhage, and the patient recovered.

Mr. Dunn pointed out that the blood which had oozed after the operation, which appeared to have been considerable in quantity, did not seem to have done any harm. The President's case was not altogether parallel, because the wound was or might be septic.

Mr. Hutchinson, in reply, insisted on the great relief that had followed the operation in respect of the pain, adding that he had purposely left the lower part of the wound loose so as to allow of the escape of any subsequent effusion of blood.

Dr. Batty Shaw, in reference to the author's third case, related the case of a woman who was admitted to hospital three days after labour. After delivery it was noticed that there was something abnormal in the abdomen, and she was sent into the hospital with the diagnosis of rupture of an ovarian cyst. She died on reaching the ward, and post-mortem they found a pale straw-coloured fluid in the abdomen without any sign of inflammation, and a collapsed ovarian cyst. He remarked that there had been no noteworthy increase in the quantity of urine passed since the accident. The fluid was thin, but that he suggested might be due to dilution with fluid secreted by the peritoneum.

Mr. Charters Symonds related the case of a child, et. 14, in whom he had recognised the presence of an ovarian tumour, but when they came to operate no trace of the tumour could be found, though there was nothing in the recent history pointing to rupture. He opened the abdomen all the same, and found the peritoneal cavity full of serous fluid, together with a ruptured ovarian cyst. The patient recovered. He also related the case of a woman, et. 35, who came in with a history pointing to rupture of an ovarian cyst. Owing to special circumstances, there was a delay of some days in operating, and when this was decided upon she was in a serious condition. She died of shock, and though there was much fluid in the abdomen, there were no signs of inflamma-

tion. He thought that if he had not operated, this patient might have recovered.

The President thought the extravasation of a thick viscid fluid with the things that it might contain might not improbably determine peritonitis. He related the case of a lady with an ovarian tumour, in which spontaneous rupture, followed by shock and ultimate recovery, took place no less than four times. After the last rupture, he opened the abdomen and removed the collapsed cyst. There had never been any peritonitis nor any adhesions.

Mr. Hutchinson, in reply, asked what was the cause of death in Dr. Shaw's case, as there was no peritonitis. He mentioned a case in which a lady ruptured an ovarian cyst, from being thrown forward in a cab.

Dr. Bertram Abrahams read a paper

ON RHEUMATIC TONSILLITIS.

an abstract whereof will be found on page 113.

Dr. Kingston Fowler was glad to have the author's confirmation of his own observations first published in 1880. He agreed that tonsillitis might be followed by rheumatism or cholera or endocarditis. He questioned the accuracy of the term "ulcerated sore throat" adding that in ordinary tonsilitis no ulceration properly so called was present. He recalled the case of a man who was admitted with quinsy for which he was being treated with chlorate of potash and iron. He remarked at the time that if he had seen this patient on his admission he would have felt disposed to give him antirheumatic remedies. Eight days after this, while still in bed, this patient had an attack of acute rheumatism. He urged that if the rheumatic nature of these throats were recognised in good time and anti-rheumatic remedies administered the attack of rheumatism might be averted. He also mentioned the case of a gentleman who had a sore throat just before going on his holidays. He went mountain climbing nevertheless and was laid up in the high Alps with a severe attack of rheumatic fever. He-deprecated the use of the term "growing pains," an expression which he suggested was a reflection on the Creator and ought to be avoided, such pains being in reality rheumatic.

Dr. Carr asked whether it was possible to diagnose these supposed rheumatic throats or whether they were to judge from the history or from the subsequent occurrence of rheumatism. In one of the author's cases the interval between the sore throat and the rheumatism was a year, and in another seventeen years. He suggested that an ordinary tonsillitis might attack rheumatic as well as other subjects. He had not been able to convince himself that anti-rheumatic remedies modified the course of these tonsillites. He defended the use of the term "growing pains" which he thought were actually as described. He himself had suffered therefrom, yet he was not rheumatic.

Dr. Lucas Benham thought any kind of sore throat might be followed by rheumatism, but the sore throat always seemed to precede the rheumatism, and even to be the cause of it. He related a case of a child who had ordinary tonsillitis lasting three days, and just when he was getting well there was a rise of temperature and a mitral murmur developed. He pointed out that when there was great ædema of the tonsils a slough might form at the point of contact which was followed by an ulcer.

Dr. SUTHERLAND admitted that it was difficult todemonstrate the connection between sore thoat and
rheumatism but some still asked whether erythema
nodosum and chorea were rheumatic manifestations.
He suggested that the tonsils might not be the only
structures attacked and ref-rred to cases in which there
was headache, vomiting, and general malaise, without
any localising sign in association with well marked
tonsillitis in patients who subsequently developed
rheumatism. He thought that the lymphoid tissue of
the alimentary tract might share in the process, and
called attention to the existence of "rheumatic appendicitis."

Dr. Toogood said that according to his experience most cases of follicular tonsillitis were of bacterial origin, and were markedly infectious. The organisms he had

met with were streptococci and staphylococci, and some-

times the short diphtheria bacillus.

Dr. Abrahams, in reply, explained that growing pains and ulcerated sore throat were merely colloquial expressions which one had to make use of in questioning patients. He was not satisfied that the antirheumatic treatment of these throats had any beneficial effect, and he mentioned a case to show that the administration of the salicylates could not be relied upon to avert the subse quent occurrence of an attack of rheumatism. He asked what could have been the cause of death in his case, assuming that the patient was not suffering from diphtheria. The non-success of antirheumatic treatment he thought was in favour of a bacterial origin. He concurred in Dr. Sutherland's remarks as to the gastrointestinal disturbance in some of these cases. He pointed out that the germs referred to by Dr. Toogood were not invariably present, and possibly the attenuated form was the true cause of rheumatism.

HARVEIAN SOCIETY OF LONDON.

THE Annual Meeting, Presidential Address, Election of Officers, and conversations of this Society took place on Thursday, January 19th.

At the close of the presidential address, the scrutineers of the ballot declared that the officers recommended by

the Council had been duly elected.

Votes of thanks were proposed and carried to the retiring officers. The meeting then resolved itself into a conversazione, instrumental and vocal music were provided by the string band of the Royal Horse Guards Blue, and by the Crichton Glee Singers, under the direction of Mr. Mervyn Dene. A collection of sporting guns, past and present, was exhibited by Dr. F. W. Cock, and Messrs. Coxeter gave a demonstration of the use of "X" Rays.

The President, Dr. Jas. F. GOODHART, delivered an

address, entitled

"OPINION THE SALT OF FACT,"

in which he dwelt on the value of opinion in things medical as well as of verified fact. He held that the promise of success satisfied the human mind as finished success can never do. Hence the fascination which treatment based on theory always exercised. Such treatment might fail from various causes, but it did not follow that the theory was altogether wrong. He alluded to the recently advocated methods of treating cancer by electrical currents of high tension, by the use of toxins, and by cophorectomy. Such methods had all failed, but who could say that the ideas on which they were based might not be "stepping stones to higher things"?

On the other hand, the theory on which treatment was based might be utterly wrong, and yet the treatment might be successful. For instance, dilatation of the heart and stomach had been regarded as due to inability of theorgans to drive their contents through obstruction ahead. But he believed that dilatation was a primary passive process, and that hypertrophy was the attempt to remedy this condition. Still, this view did not interfere with the success of treatment based on a 1 opposite

assumption.

The lecturer then referred to the statement recently made by Dr. Sidney Phillips that disease has changed in type. He fully concurred in this view, and illustrated the changes, not only in the case of enteric fever, but in other diseases, such as diphtheria, pneumonia, and appendicitis. He compared the accounts of influenza by Huxham, in 1733, and of morbilli, by Sydenham (1670), with the phenomens of those diseases in their present type. The change of type was apparent not only in diseases but in man, and thought and even in the expression of thought. This was exemplified in the case of painters, novelists, and other writers. Man and his view of his environment were in a constant condition of change.

One had only to look at the pictures by Rembrandt and other old masters, or read the novels of Burney, Thackeray, and Dickens to see how widely their outlook on nature differed from that of present-artists and

writers.

He had entitled his address "Opinion the Salt of

Fact." In the study of disease he believed there was a legitimate sphere for the nebulous phase of thought—although the fruit of speculation might often seem unripe.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, January 29th, 1899.

A NOVEL FEATURE IN ARTIFICIAL AIR.

AT the meeting of the Académie of Médicine M Laborde read a paper on a chemical substance which by its simple contact with air vitiated by respiration regenerates it completely, restoring to it its first qualities. In other words this substance removes absolutely the carbonic acid from the foul air, as well as the water vapour, and irrespirable products, and renders to it in exchange the exact quantity of oxygen required. From the first series of experiments it was discovered that six or eight pounds of the substance would keep alive in a space hermetically sealed (a submarine boat or a diving bell, for instance) a healthy man during twenty-four hours. Besides, the product was capable of rendering good services to medicine, as with a few grammes of it a dozen litres of oxygen could be obtained instantaneously.

APPENDICITIS.

M. Schwartz said that he differed from the opinions expressed by some of his colleagues, approving early interference in every kind of appendicitis. He had seen over thirty cases get well without any operation, that was to say, where no abscess had formed. Otherwise they were all agreed on interfering where suppuration was suspected. In every other case he deferred operating as long as the pulse remained good and paralysis of the intestine had not set in. As to the operation, he followed the method of Max Schüller, which was to make the incision along the outer edge of the rectus muscle, and with this incision he had never witnessed eventration.

M. Lejars said that there existed a tendency to believe that acute appendicitis should be treated medically, while an operation should be reserved to the period when the acute symptoms had subsided. The idea might hold good in many cases, but sometimes immediate interference was necessary to save the patient, as the usual signs of the presence of an abscess were not necessary to the existence of extensive suppuration. leaving aside cases of perforation which required immediate surgical treatment, there were cases of septic appendicitis which killed rapidly patients if they were not operated on at once. M. Reynier said that as long as no alarming symptoms were present he treated the patient by rest and the application of ice to the abdomen.

WHOOPING COUGH.

Whooping cough, according to M. Lagounne, is an infectious malady due to a special germ, transmitted directly through the expired air or indirectly by infected objects. Consequently its propagation is easy and rapid-Blache said that whooping cough attained its maximum of frequency between the ages of three and four—that was to say at the period when the children are thrown together in infant schools.

Temperature and seasons had no influence on the germ itself, and if the affection was more intense in winter than at other periods of the year the cause resided

solely in the fact that the patients were confined to the house more, and lived consequently in a vitiated atmosphere; the open-air diminished, on the other hand, the gravity of the disease.

As to the treatment, it should be entirely external, as the administration of remedies usually prescribed in these cases arrested the fits of coughing by paralysing the expiratory muscles

As soon as the affection is recognised, the bedclothes and all the wearing apparel in use, as well as the carpets and the curtains, should to sprinkled several times a day with an antiseptic solution, even that of corrosive sublimate (1—1,000). The patients should live as much as possible out of doors, and when feasible they should not occupy the same apartment night and day.

All linen clothes, and, in fact, every object soiled with the expectoration, should be plunged into boiling water, and afterwards washed with antisepic solution. In order to prevent the production of the germ and to obtain the antisepsy of the respiratory apparatus and of the circum-ambient air, the clothes of the child in proximity with the mouth (the front of the chest, the sleeves) should be sprinkled several times daily, while the same should be done in the evening to the pillows, sheets, and coverings near the head of the patient.

The solution employed by Dr. Lagounue is:-

Sulphuric Ether, 400;
Acetic Ether, 150;
Proof Spirit, 300;
Salol, 50;
Phenic Acid Crist, 15;
Essence of Lavender, 25;
— of Winter Green, 25.

Germany.

[FROM OUR OWN CORRESPONDENT.]

Berlin, January 27th, 1899.

At the Dermatological Society, Hr. Rudolf Isaac spoke on

IVES' COLOUR PHOTOGRAPHY IN DERMATOLOGY.

Ives photographed the object three times through a green-violet-red slide, with a period of exposure corresponding to the actinic activity of the colour filter. Glass dia-positives were prepared from the negatives formed on plates which were receptive to colours. These were viewed either in the skiopticon or chromoscope through three correspondingly green, violet, and red colour filters. In the skiopticon were three objects, which gave three images which, superposed, gave an image in natural colours. The chromoscope was a kind of stereoscope that, by a peculiar arrangement of mirrors. permitted the three colours to be thrown over each other. Some dermatological photographs were shown, in which a certain amount of success had been attained. The hope was expressed that the present technique would be improved upon.

Hr. Le Casper followed with a note on

THE ACTION OF SILVER NITRATE ON THE URETHRAL MUCOUS MEMBRANE.

The speaker had made experimental observations as to whether the instillation of strong solutions of silver nitrate produced permanent cicatrices in the urethral mucous membrane. Observations on the human subject

were not at hand, as scarcely any surgeon had the opportunity of investigating anatomically the urethra of a patient who had been treated with silver nitrate. His experiments were on dogs and rabbits, and the solution employed were 1 to 2 per cent. solutions, the injection being made in the usual way, and at the usual intervals of time. His investigations began in 1894. Thirty-five instillations were made on six animals, and two were killed at six months, two at nine, and two at twelve. On examination there were no traces of inflammation in either mucosa or submucosa, both layers were filled with nodules and flakes which were either silver or combinations of it. The flakes dissolved in potassium cyanide. In animals, on the other hand, that had fifteen 1 per cent. solutions of chloride of zinc injected the epithelium was, in some cases, grown to the submucosa, in others the function of the epithelium was changed; the submucosa contained fresh round cell deposits in some places, in others the mucous surface was destroyed.

Immediately after the silver application the upper layers of the mucous membrane were converted into a homogeneous brown cautery slough, and between the spots were collections of round cells. There were signs of inflammation also with deeper tissue layers. After four days nothing more was seen of the silver that had been applied, and eight days after every trace of interference had disappeared. The speaker then passed on to the theory of the action of silver nitrate. It consisted in destruction of the upper layers of epithelium and consecutive irritation. The irritation was a deep action, so that silver fulfilled the indications that were supposed to render the newer preparations preferable. His investigations had shown that the fear that Gyon's instillation of silver would cause stricture was groundless. The old tried remedy had now its justification experimentally. The note was illustrated by excellent microscopic preparations.

Accidental Wounds of the Internal Jugular Vein.

Two cases of this were observed by Dr. Oppel and reported in the Deutsch Med. Zeit. In both cases the vessel was only incised. The treatment consisted chiefly in double ligation of the vessel above and below. Both patients recovered without any serious complication. In studying the literature of the subject, Dr. Oppel found in thirteen similar cases all recovered, and under double ligation of the vessel. He also met with three cases that were treated with prolonged digital compression. These also did well. In four other cases the treatment was by tamponnade of the wound. Three of these died either from hæmorrhage or sepsis, and only one recovered. One case was met with that was treated by ligature of the common carotid, and this also ended favourably. Twelve other cases were, however, met with, in which no treatment was carried out, and these all ended fatally. To these thirty-five cases the author adds the fifteen observed in the North American war. This gave a total of fifty cases, thirty of which were fatal. During the antiseptic era are eleven cases, nine were treated by ligature, and recovered, two had no treatment and died. The mortality here was 18 per cent., whilst in the preantiseptic era it was 58 per cent. The chief danger in these cases did not lie in the primary hæmorrhage as may be expected, but n the secondary, which was mostly associated with infection in the wound. Admission of

air into the vein was certainly a very dangerous complication, but it was one of very rare occurrence.

OPERATION IN SEVENTY-NINE CASES OF EXTRA-UTERINE PREGNANCY.

Wratch contains a paper on the subject by Dr. Strauch, the whole forming a plea for operation, and early operation in such cases. After giving an account of the supposed ætiology of ectopic gestation and the diagnosis of the condition, he goes on to quote Martin's statistics as to prognosis. These were to the effect that in 278 cases the mortality was 67 per cent. in those treated expectantly, whilst the recoveries were only 33 per cent. Of 636 cases operated on 20 per cent. died and 80 per cent. recovered. In cases therefore in which a diagnosis of extra-uterine gestation had been made the clear course in duty was to operate at once. The earlier the operation was performed the easier it was and the better for the prognosis. If abortion or rupture has already taken place, the bleeding part should be made accessible, and an attempt be made to arrest the bleeding. It was a grave mistake to give stimulants in such cases. The feeble condition of the heart was a factor that favoured arrest of hæmorrhage. Stimulants raised the depressed blood pressure, and excited fresh hæmor. rhage. Large quantities of saline fluid also should not be given before operation. The vessels should first be ligatured and then the system might be filled up with salines. The extravasated blood should be removed from the abdomen, as much as possible. When the operation was by abdominal laparotomy a more careful examination can be made, and cleansing can be more thorough, while if from the vagina it was less dangerous, especially after decomposition has set in. In the second half of tubal pregnancy laparotomy was the usual way. Among the author's 79 cases there had not been a single death. The youngest patient was 21 and the oldest 46. The oldest pregnancy was one of seven and a half months, the youngest one of a few weeks. In the first case the child lived for half an hour after extraction. The pregnancy was in the right tube 31 times, in the left 39. The operation was by laparotomy 63 times. Six patients had conceived and borne children after the operation.

At the Society for Scientific Medicine, Königsberg, Hr. Ascher showed a

STABBING WOUND OF THE HEART,

Along with other serious injuries in the left ventricle. there was also a perforating wound about 2 ctm. in length close to the septum, which was closed by a thrombus. The man lived 20 hours after the infliction of the injuries.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, January 28th, 1899. TEUCRIN AND TUBERCULOSIS.

AT the Medical Club, Erheim exhibited two cases which he had treated with teucrin Mosetig for tuberculous ulcers. The first was a boy of ten years, with an intractable ulcer in the mucous membrane of the cheek; the second was a young woman, æt. 24, with a similar ulcer on the under lip. Both ulcers were treated by subcutaneous injections of the extract of teucrin (Extr | M.P., the oldest practitioner in Blackburn, we underteucri scordii depur.), which was injected into the circum-

ference of the ulcerated tissue. The smaller sore healed in a few days, the larger began with the common cement of the injections to granulate rapidly, and healed up within fourteen days. This ulcer had existed for four months previous to the injections, notwithstanding the heroic treatment adopted before that time. He showed a third case of the same class, which had not been previously treated, that occurred on the under lip in the form of lupus, accompanied by lymphadenitis. The boy was 14 years of age. The half of the left lip was destroyed by the ulcer, which had a firm infiltrated base and margin; on the right half was a smaller ulcer of a similar character, which the microscopic examination proved to be tuberculous. He was treated in the same manner as the two previous cases, with equal success.

Max Kahane recorded a case of a large "cold" abscess which he had treated with teucrin injections, and which rapidly receded, leaving a small fistula leading into the spinal cord. He thought that the activity of the teucrin was instrumental in converting the chronic inflammation into an acute inflammatory condition.

OPERATONS ON GALL-STONES.

Schnitzler reopened the discussion on Riedel's paper, which was read some time ago before the Society, in order to criticise some of the opinions then attempted to be established. He disagreed with Riedel when he would not operate on a long standing gall-stone which had become wedged in the neck of the gall-bladder in the cystic duct, or the ductus choledochus, which though not producing hepatic congestion may afterwards produce inflammation with colic attacks. He quite agreed with Riedel that large gall-stones lying in the gall-bladder seldom produce inflammation, though small ones in the former position will, and often do, produce in. flammatory conditions Schnitzler also believed that the "perialienitis" of Riedel was provoked by the congestion which was the result of active inflammation in the fibrous tissues of the gall-ducts which may only have been temporary or transitory in its effect. This congested form of inflammation is not uncommon in other organs which is usually associated with fever and rigor where neither sepsis nor nephritis is present. Schnitzler himself had a case of this kind where high fever existed for months, but after the removal of the gall-stone it suddenly disappeared, leaving the kidneys entire and no sign of pus anywhere. Schnitzler cannot agree with Czerny that a large number of the cases of cholelithiasis contain sugar or some other reduced substance in the urine. Ileus, or colic of the bowel, is also a rare condition after a gallstone has entered it. In proof of this he recorded four cases coming under his own observation. The first appeared with septic phenomena, while the stone was found by operation in a fold of the bowel, but nowhere was inflammation to be found. The post-mortem revealed an abscess in the gall appendages from which the sepsis originally entered the ducts, which led to the formation of the gall-stone. In another case operated upon the stone was found after a post-mortem examination in a fold of the large intestine, while in the small intestine was observed a large decubitus ulcer, where the calculus had apparently lain for some time.

DR. MORLEY, brother of the Right Hon. John Morley, stand, is seriously ill.

Riviera Mealth Resorts.

(From Our Special Correspondent.)

NICE.

The causes of the poor season (so far) on the Riviera have been variously assigned to the typhoid rumours about Nice, and to diplomatic difficulties about Fashoda, Madagascar,

That the unusual drought of last summer shortened the well-water supply at Nice, and threw the poorer and less cautious classes of the population upon more or less impure sources for drinking water, thereby occasioning fevers in the older and in the outlying districts of Nice during the months of September and October, is beyond question. The rains of early November remedied this, and carried off any danger therefrom. When here late in November, I found the normal healthiness of the place fully re-established. Squabbles with a leading American journalist about rents and bulletin-boardings, want of tact and dilatoriness of the municipal authorities in some other matters, led to newspaper controversies far and wide. But if these local issues were the cause of the diminution in the number of English and other foreign visitors to Nice, why did other Riviera resorts suffer?

Hyères, with a saline-tempered atmosphere, yet with exemption from a too close proximity to the sea, and enjoying an enviable reputation for a century back, is a most desirable winter home; Cannes, with its old time prestige and English comforts; Valescure and Cap Martin with their pine-forests; the Cap d'Antibes, a rocky and unmistakably healthy spot; Grasse, on its picturesque hill-slope amidst the purest mountain breezes-inland places with excellent sanitation, seawashed towns equally well cared for, mountain side hotels, like the favourite Grand, of Grasse-situations of varied positions in the Riviera, and of acknowledged heathfulness, all alike have been short of guests.

Even popular winter resorts, far distant from the Riviera, likewise suffered. The visitors were as scanty even at Pau, with its admirable climate and unquestion able salubrity, and at "bright, beautiful, brilliant Biarritz," with its atmosphere of rare purity, its many gaieties, and its health-giving ocean tides. One would have thought these and similar distant resorts should have benefited from any local difficulties at Nice

Then as to diplomatic differences between France and England, if these kept our countrymen from French shores, why did not Italy profit? All along the Italian Riviera come equally poor reports of few visitors this season. Except, perhaps, the recently enlarged and beautified Hotel Angst at Bordighera and the popular Royal Hotel at San Remo, I know of no Italian hotels which have not had to complain of too few guests. Farther afield, also, from Corsica, the Canary Isles, Madeira, Cairo, from every winter resort the complaint is the same.

And how about the English winter homes? Are Bath, Hastings, Eastbourne, Brighton, Torquay, Falmouth, &c., having brilliant seasons? Surely the thousands of our British people who usually fill winter residential stations abroad should this season have crowded the home stations to overflowing. Probably the true cause of a scarcity of English visitors and of tourists all over the Continent and elsewhere, is that the autumn and winter have been "stay-at-home" seasons.

Whatever the causes, the result should be beneficial. to the future welfare of Nice. Improvements projected and promised years since, are now to be efficiently carried out by the municipal authorities and the leading landowners, with the advice and assistance of local scientists and physicians. These improvements will be of great permanent value to Nice. And not Nice alone should benefit. The whole of the French Riviera has had an opportune "object lesson"! In recent years the chief aim, apparently, of the authorities and managers has been to cater for their pleasure-seeking guests, and at the same time gratify the native populace who dearly love

> "Pomp and Feast and Revelry, Mask and antique Pageantry."

As the Medical Press and Circular said a year ago, "the glitter and the glare of fashionable life on the Riviera has unfortunately of late years thrown too much into the shade the value of the merits and attractions of this coast for the invalid, the delicate, the world-wearied, the aged and the convalescent." it is these who have created and who chiefly contribute to the prosperity of the Riviera They come here early each "season," and remain the latest in the spring; while the more showy and noisy guests "on pleasure bent" flock hither only for February and March alone. The lessons of the present winter, with its scarcity of British and other long-residing visitors, cannot but make the more "serious," influential, and reflecting property-owners, business-people, and hotelproprietors along the Riviera recognise that it is the invalid, the delicate, the rest-seekers, the old, and the convalescent who constitute the main support of its financial prosperity, and that it is for them chiefly provision should be made.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

CHOLFCYSTOTOMY.—Mr. CARLESS operated on a woman. æt. 40, who for some months had suffered from abdominal symptoms of some severity. She had been seized time after time with attacks of colicky pain referred to the right iliac region, and a lump of some size had been noticed there for a considerable time. It had, however, varied in size, and on examination a few days before operation it was much smaller than it had been previously. whilst on the patient's bowels being cleared by medicine immediately before the operation, there was no lump to be felt at all; at the same time, the patient had lost flesh considerably, and the pain and colic had been so severe that there could be no question as to the existence of some focus of obstruction somewhere in the bowel. After the usual purification of the abdominal wall, an incision was made somewhat similar to that utilised in the removal of the appendix, but slightly nearer the middle line, by which means the rectus was exposed, and the peritoneum opened after separating the fibres of the muscle longitudinally. The cæcum protruded at once, and although it and the neighbouring portion of the ascending colon were found to be healthy, yet the longitudinal muscular bands were so extremely hypertrophied as to cause the bowel to be curiously corrugated, evidently indicating that there was some obstruction to be overcome; the small intestine was quite healthy, although portions of it were in a state of extreme spasmodic contraction

which, however, could be overcome by applying hot saline solution and pressing flatus onwards. The uterus and its appendages were found normal, as also the kidneys and spleen. The large intestine was then traced round upwards from the sigmoid flexure and nothing was noticed till the hepatic flexure was reached, when the hand came in contact with a tense elastic swelling evidently a greatly distended gall-bladder. The parietal incision was promptly enlarged upwards to the costal margin, and after the intestines had been guarded by a suitable arrangement of cyanide gauze soaked in hot sterilised saline solution, the gall-bladder was drawn up out of the wound. It was found to have considerable adhesions to the hepatic flexure of the colon, thus explaining the colic and obstruction phenomena from which the patient had suffered; these adhesions were carefully divided, and by this means the gall bladder was traced back to the cystic duct in which a large calculus was detected. The gall-bladder was now tapped with a large trocar and cannula, and an ounce or more of yellowish puriform fluid withdrawn; after removal of the cannula the gall-bladder was opened sufficiently to allow of the introduction of the index finger, and, after a little manipulation with a lithotomy scoop, a rounded gall-stone, the size of a large marble, was withdrawn. A careful investigation with fingers and a long probe having led to the detection of no other calculi a large drainage tube was stitched into the gallbladder, which was then fixed to the abdominal wall, whilst the rest of the external wound was closed with deep interrupted sutures and a superficial continuous suture of catgut. Mr. Carless remarked that in this case the diagnosis before operation was very uncertain and the woman had complained of some menstrual disturbance, but Dr. John Phillips had carefully examined her, and found that the uterus and appendages were normal. There was also some doubtful history of hæmaturia, but nothing could be felt in either loin. The lump which the woman had noticed was evidently due to distension of the cæcum, since it had varied from time to time and its presence had always been associated with severe colic. There had been no history of biliary colic, and no jaundice, and the gall-bladder, though distended, was not very obviously palpable, hence a provisional diagnosis had been made of carcinoma of the bowel (based on the loss of flesh, the existence of a lump, and the recurrent attacks of colic and pseudo-obstruction), or of some obstruction in the course of the colon. It was, therefore, obviously wise to commence with an exploration of the cacum and its adnexa, so the incision mentioned above answered admirably this purpose, whilst it permitted the whole abdomen to be explored. The condition found round the gall-bladder sufficed to explain the chief symptoms of the patient, although not those connected with the menstrual disturbances. Only one calculus was found, and probably, since it was rounded and had no signs of facets, no other was present. In several preceding cases Mr. Carless had entirely closed the gall-bladder after removal of calculi, and preferred to follow that practice if possible, but in this particular instance the fact that the contents were puriform led him to make a temporary fistula. It has since been ascertained that pus cells were present in the fluid and also

large numbers of diplococci.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular. Fublished every Wednesday morning, Price 5d. Post free, 54d. ADVERTISEMENTS.

FOR A SERIES OF INSERTIONS:—Whole Page, thirteeu insertions (weekly, fortnightly, or monthly), at £3 10s. 6d.: twenty-six insertions (weekly or fortnightly) at £3 3s. 0d.: flfty-two insertions (weekly) at £3 each. Half Page, thirteen insertions at 35s.: twenty-six at 32s.: flfty-two insertions at 30s. each. Quarter-page, thirteen insertions at 18s.: twenty-six insertions at 16s.: flfty-two insertions at 15s. each. "SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 1, 1899.

LUNATICS AS PRIVATE PATIENTS.

A RECENT trial has brought into prominence the subject of the treatment of lunatics in private asylums. The immediate object of the legal proceedings was the alleged reception of a person of unsound mind by a medical man without a licence. With this more particular aspect of the larger question we propose, in the present instance, to deal because of certain occurrences connected with the trial, which seem to require plain-speaking on the part of the medical journals. The Lunacy Acts clearly accept the principle that no person of unsound mind should be confined in an unlicensed house, a precaution that is absolutely needed for the protection of the liberty of the subject against the most serious possible Anything that is likely, therefore, to hinder or hamper the carrying out of the machinery of licensing and of its connoted inspection must be regarded with instant suspicion and counteracted with firm authority. If we accept these propositions, which appear incontrovertible, it is not a little curious to witness the attitude of a leading lunacy expert arising out of the trial to which allu-Those who are interested sion has been made. in lunacy matters will readily recall the facts of the case. As the result of profound convictions only could a gentleman in so eminent a position publicly traverse one of the fundamental principles of the Lunacy Acts. That he should attempt to justify his active opposition to the salu tary measure that is framed to prevent the shutting up of a sane man as a lunatic, and start a public subscription to defend a medical man charged with an infringement of that provision, savours

of a temerity happily not often met with in the law-abiding profession of medicine. In these latter days the violent methods of Wat Tyler have fallen into disrepute with those who seek to reform laws that are not to their taste. From our point of view, which we venture to imagine has the support of nine tenths of the medical profession, and the vast majority of the outside community, there can be no question as to the wisdom of establishing absolute official control of lunatics in order to prevent such conspiracies against property and personal freedom as formed the favourite tilting post of the once popular novelist, Mr. Charles Reade. Indeed, the question has often been raised, more especially in recent years, as to whether the private licensed house should be permitted to exist at all, and whether all insane persons should not be taken under direct State control in public asylums. The reasons, both for and against a radical and far-reaching step of that kind, are numerous and weighty. Without entering into them at length, however, it may be stated that one of the most plausible adverse arguments is that well-to-do lunatics would not in that case be able to obtain the best conditions favourable to their recovery. It is not clear, however, why the State should be unable to conduct what is usually regarded as an extremely remunerative organisation and combination of special treatment and capital. Then, again, there is the ever present fact that it is against the interests of private institutions to lose their patients. At the same time, we are glad to believe that with few exceptions the private asylums of this country are above reproach, and we are willing to admit that the proposal to do away with them in favour of State institutions is, in the present stage of social progress at any rate, an unworkable counsel of perfection. That the lunacy laws are not without flaws is pretty widely acknowledged, and it is to be hoped that Parliament will one day find time to pay a little attention to that and a hundred other important social matters connected with the medical profession that have long since been ripe for reform. The central control of the lunacy laws, like that of the Local Government Board, and of the General Medical Council, we regard as inefficient, slothful and conducted on more or less fossilised methods. So far as the Lunacy Commissioners are concerned, it would be impossible to do the work of inspection properly without multiplying the staff by several times its present strength. The "strongest Government of modern times" has irons in the fire in all quarters of the world, but has hitherto done little for any of the matters affecting the medical profession, either directly or indirectly. Their only attempts in that direction, namely, the separate treatment of certain classes of disabled metropolitan pauper children, and the abolition of compulsory vacc nation have certainly not been calculated to stamp their administration as memorable in the annals of medicine But an opportunity still offers while Poor-law administration is wedded to that

of the public sanitary service, while the General Medical Council remains practically autocratic, and while lunacy administration lags behind the times.

MR. HUNTER'S APPEAL.

MR. HUNTER, though dead yet speaketh, and he technically appeared before the judges of the Queen's Bench Division on Tuesday of last week to urge his appeal against the decision of the justices who punished him for making use of the designations physician and surgeon, or, to be strictly accurate. for calling himself a physician, he being only a licentiate of the Society of Apothecaries. The question before the judges was whether the right to practise medicine conveyed by the licence of the Society of Apothecaries implied the right to the description of physi cian, or, in other words, whether this title means merely a person who practises medicine or belongs exclusively to the holders of a particular diploma-Two judges have now decided that the title belongs of right to "persons in the highest grade of medical practitioners," but this leaves much that is vague because it is not specifically declared what constitues the "highest grade." We are still at liberty to wrangle whether the title physician is restricted to fellows of the Royal Colleges of Physicians, whether members of those bodies share that privilege, or whether the possession of a degree in medicine does not establish a supremacy over the body of non-graduate practitioners. Even more, it would be brutal to refuse the title to licentiates of those bodies for they have received a licence to practise physic, and he who practises physic is presumably a physician. If not, what is he? St. Luke is described in Holy Writ as a physician—a title to which, in the view of Her Majesty's judges, he has no right-and we commend this observation to the notice of future editors of "revised editions" of the New Testament. Mutatis mutandum, if it be an offence for others than fellows or members of the Colleges of Physicians to style themselves physicians, it must be equally obnoxious for persons to call themselves surgeons who are not members or fellows of a College of Surgeons, though this point has not come up for discussion on the present occasion. judges have studiously and successfully avoided deciding more than they were asked to decide-viz., whether a certian licentiate of the Society of Apothecaries was entitled to make use of the title physician, and, as already stated, they have decided that he had no such right. The fact that they quashed the conviction on the ground that the defendant had not "wilfully" made use of a false designation is interesting but not very instructive, but it may, perhaps, be construed as a rejoinder to the carefully worded circular issued by the Apothecaries' Society informing all and sundry that their licence confers the right to practise medicine, surgery, and midwifery. For our own part we have no hesitation in expressing the opinion that the decision is absurd in principle, if sound in law. All it does is to withhold

from licentiates of a certain qualifying body the right to use a particular designation which, on the face of it, only describes their calling as practitioners of physic. It stands from this point of view, on all fours with the popular prefix of "doctor," which, by general consent, is applied to anyone who practises medicine, and even to those more or less distantly connected with that calling. We see no objection to particular diplomas conferring each its particular titular designation, but we are not manifestly nearer this consummation in virtue of this decision Mr. Justice Channell made one remark which shows very clearly the confusion which exists in the minds of the laity on the merits of these intra-professional questions. Commenting upon the case of Regina versus Baker, he mentioned that the qualification in that case was of an earlier date than 1886, and did not authorise the defendant to practise surgery "which' said the judge, "is a department of the practice of a physician." This is a reductio ad absurdum for the rules of the Colleges of Physicians expressly forbid, or at any rate forbade, the practice of surgery by their fellows and members. The General Medical Council has scored a point, it is true, but the painful circumstances under which this particular prosecution was undertaken still remain to be explained, and we say explained, because justified they cannot be.

THE SANITARY INSPECTION OF SCHOOLS.

THE right of a local sanitary authority to visit and inspect all and any buildings in the district has always been a moot point, that is, in the absence of the existence of "a reasonable cause." In the case decided by a metropolitan police magistrate last week in favour of the managers of the North London Collegiate School it is laid down that the sanitary inspector, as such, has no right of entry to a school building unless he can "show cause." We note with satisfaction that the opposition offered by the managers of this institution is not based on any abstract objection to sanitary inspection, but on a distrust of the particular sanitary authority which, in their opinion, is ill-fitted to offer an opinion on the subject. It will excite a feeling of surprise in the minds of many who are not conversant with the intricacies of our much vaunted sanitary legislation to find that compulsory, methodical inspection of school premises does not find a place in the programme. If the health of our factory operatives is thought worthy of consideration surely that of the rising generation is not less so; indeed, it might well be considered to warrant closer scrutiny seeing that the scholars are not of an age to form any opinion on the subject. The elementary schools are duly kept under observation, but private schools and secondary schools are regarded by the law as private houses, yet it is precisely in the case of private or quasi-private institutions that effectual surveillance is most necessary. The time is probably not far distant when no buildings will be allowed to be used for school purposes until, after proper inspection, they have been admitted to registration,

such registration comporting subsequent systematic supervision by the local sanitary authority. When this subject comes up it would be well to enact similar. or even more drastic, provisions in respect of private-adventure hospitals, which also presumably come under the heading of "houses." Englishman's house has long since ceased to be a castle as against the sanitary inspector, but even such mitigated rights as the householder may have preserved ought to be abrogated when he uses his house for other than private and residential purposes. It is obvious that special 'egislation is called for in the direction of completing and extending the powers at present possessed by sanitary authorities for the inspection of buildings for whatever purpose they may be used. How is the authority to become aware of the existence of unsanitary conditions unless every facility for inspection be afforded? There are many things short of blood-boiling or soapmaking that call for remedy, and the fact that nauseating emanations are not complained of by no means justifies the assumption that all is for the best from a sanitary point of view.

Rotes on Current Topics.

A Plea for All-Night Pharmacies.

THE large towns of Great Britain are singularly behind those of the Continent and especially of the United States in respect of the facilities available for procuring medicine at night. The medical practitioner, poor, man, has to comply with every request for assistance irrespective of the hour of day or night but when he has done his share of the work and has prescribed the appropriate remedies it may be next to impossible to get the prescription made up. We should be loth to add to the burdens of the followers of an already hard-worked and ill-paid calling, but one would have thought that the spirit of commercial enterprise would have prompted a certain number of pharmacists to cater for the night work. One or two attempts of the kind have been made in London, but they have, we believe, been abandoned in deference to reasons of an extra-professional kind. Night work is, of course, not popular, and extra-remuneration would alone induce anyone to devote himself to this branch. Apart from this there appears to be a difficulty in exercising sufficient control over the night operators, and this is probably the most serious obstacle. Failing private enterprise we should, perhaps, be entitled to look to municipal authorities to provide the necessary facilities, the lack whereof may render nugatory the presence of the doctor. We are aware that in many instances there is a resident assistant who is supposed to respond to night calls, but those who have had occasion to put this to the test of experience know to their cost how illusory this assumption is in point of fact. An instance is given by a correspondent who, armed with a presc intion at 3 a.m., applied in vain at sixteen pharmacies. Such a state of things

constitutes a positive danger, and is little short of a scandal, and it is, moreover, a strong argument in favour of medical men retaining the dispensing of medicines in their own hands.

Prevention of Unnecessary Noises.

THE inhabitants of cities and towns will read with interest the news that the proprietor of a certain noisy bird, to wit a cockerel, inhabiting the romantic shades of t. John's Wood, has been fined for not having deferred to a warning request conveyed to him by three of his neighbours whose rest was disturbed by the animal aforesaid. We gather from the evidence that a cockerel is a male fowl, a fact of which we were ignorant, and which the dictionary did not assist us in discovering. Now anyone who has ever heard a cock crow at a distance of less than one hundred feet will agree that a rooster, to make use of an American equivalent, which begins to practise crowing at 3 a.m. is indeed an infliction not to be borne if any means are available of inhibiting the same. The magistrate appeared to apply the law with some reluctance, observing that the by-law was passed to meet the difficulty of a class of persons who, "instead of deriving pleasure from the natural noises of animal life found these noises a source of exquisite torment and disquiet." Does the worthy magistrate himself derive any pleasure from a cock-crow at 3 a.m. or even an hour or two later 2 Does he lie awake o' nights savouring the long drawnout sweetness of the amatory strains of feline marauders? There are natural noises which are agreeable and others which are not so, but there are, indeed, few natural noises which are suave to the human ear in the early hours of the morning. The wear and tear of life in great cities will be vastly lessened when all unnecessary noises are sternly repressed, and we thankfully accept this by-law as an instalment on account of further steps in the same direction.

Medical Fees among Poor-law Medical Officers in Ireland.

THE misrepresentation, by the aid of which the Irish Local Government Board seeks to choke off the agitation for the reform of the dispensary ticket, has again been repeated in the Dublin papers by a "J.P. for two counties." That misstatement is that the Poor-law medical officers of Ireland are prevented by professional etiquette, or some other cause, from accepting less than £1 a visit, or £1 for first visit. All we need say is that, if there be any such etiquette rule, it is almost universally disregarded, and there is not a district in Ireland in which difficulty would be experienced in obtaining medical relief at such reasonable fee as suits the patient's capacity. We declare that the above statement is absolutely false, and we are astonished that the Local Government Board-whose inspectors must know that it is soshould use it as its excuse for resisting reform. Dispensary officers are not altogether fools. They know, as a rule, the financial calibre of every man in their district almost as well as he does himself. They know that some are well able to pay £1

every visit, and others only £1 at first visit, and they are perfectly right to exact such fees from such persons, who, unfortunately, are very scarce in most districts. As for the other patients, is it likely that a dispensary doctor will drive them into the net of a rival practitioner, or force them to resort to the "ticket" by demanding an excessive fee? In ninety cases out of every hundred he accepts as fee any reasonable sum-even down to half a crown-which he knows the patient can pay, not what the patient says he can pay; a d in this way no deserving pay case is ever left without medical attendance. But, in fact, this argument is entirely outside the question. The Poor-law Medical Officers of Ireland have never objected to attend on ticket persons whom they consider unable to pay the full fee of £1. If any such officer is in such demand that it does not pay him to attend for less than that sum he can refuse to do so, but, in such case, he should not and does not complain of having to attend on "ticket." What he does complain of is that most of the patients whom he knows to be perfectly well able to pay many pounds are-through the corruption of the system maintained by the Local Government Board-enabled to obtain gratuitous attendance. We hope we have heard the last of the friction to which we referred. If it were ten times true it would not justify the scandalous abuses of the Irish Dispensary ticket system.

Bath and its Fever Hospital.

THE sanitary administration of Bath is having a somewhat exciting time in consequence of the action of its able and energetic Medical Officer of Health, Dr. Symons, who has recently drawn attention to the management of the Fever Hospital. Of course, in a matter of this kind there is usually something to be said on both sides. The Bath Chronicle, however, says that something in a way that seems hardly worthy of a leading and responsible newspaper. Thus, in its issue of the 26th instant, it speaks of the "traducers" of the hospital. That is begging the question with a vengeance, and it says little for the candour of an editor who assumes an attitude of that kind at the outset of criticism on a matter of public interest. The issue of Keene's Bath Journal, again, for the 21st ultimo contained an article on this same Statutory Hospital. in which the faulty state of the buildings was admitted. In discussing past work the following passage occurred:-" The importance of the present system may be gathered from the fact that from 1882 to 1894 no fewer than 1,734 patients were treated at the hospital, and out of this number there were only 17 deaths." That strikes one as a most favourable percentage, but on further inquiry we find that between the years of 1884 and 1894 inclusive, there were not less that 71 deaths—a very different rate. Clearly, then, the citizens of Bath can hardly trust implicitly to the tone and accuracy of their journals in this matter. The Medical Officer of Health for the town, in the course of his plain and bounden duty, has passed various criticisms upon a public institution,

to maintain the efficiency of which is one of the most important of his functions. An affair of this kind should be approached in a spirit of broad municipal progressiveness and not with the narrowness of the vestry partisan. Twenty years ago Bath ran up a number of huts in a panic when small-pox invaded the city. Those temporary buildings survive as the Statutory Hospital under the charge of a superintendent who, we learn, is a pluralist of a most exalted order. On general grounds we should say that it is unwise to appoint a sanitary inspector superintendent of a fever hospital. A staff of ten or thereabouts (the exact number is in dispute) hardly requires any supervision beyond that of the visiting medical officer. Why the latter is chosen from the local medical men to act as Dr. Symon's deputy is somewhat of a mystery. It is to be hoped that the whole facts of the case will be made public in some authoritative manner.

Unionists and Non-Unionists.

THE medical profession may be broadly divided into unionists and non-unionists. Let us hasten to explain, in order to avert the wrath of those to whom trades' unionism is a thing accursed, that we speak of the members of the Medical Defence Union and kindred societies, and, on the other hand, of those who keep their half-guinea subscription in their foolish pockets, and fail to realise the concrete fact that in the Medical Union is strength. When one reflects upon the work of that body—and of its offshoots—it is a matter of never ceasing wonder that so much could have been accomplished within so comparatively short a period of time. During the last few years there has been a great diminution in the number of actions for malpraxis, and in black mailing charges brought against medical men. What other condition has come into existence to account for that happy change? None that one can recall, save the birth and the strong and rapid growth of the defence societies. Where the busy practitioner was formerly exposed to the anxiety and cost of litigation which could not fail, whatever the issue, to do him damage both in purse and in reputation, he is now able to summon to his aid a powerful organisation backed with unlimited money and special experience. That is to say, he may command that refuge if he be a member, and, although we speak in glowing terms of the increased roll of membership. yet it is well to note that a large majority of the profession is still to be reckoned among the nonunionists. Let the coming generation see to it that every one of them stands shoulder to shoulder with his brethren, at any rate in this elementary matter of insurance against blackmailing.

DURING last year 5,920 persons committed suicide in the United States, 4,286 men and 1,634 women. This number includes 44 doctors. With respect to the quietus selected, 2,526 chose poison, 2,037 preferred firearms, 787 hanged themselves, 354 chose drowning, 26 asphyxia, and 75 died as the result of self-inflicted stabe.

The Municipalisation of London.

THE Government Bill for the municipalisation of London, which will be introduced early in the approaching session, deals with many matters of interest to the community generally, but there is one aspect of it which we may consider here, and that is the uses to which the various local municipalities might be put in furthering the interests of the hospitals within their districts. Under the Municipal Corporation Act each London hospital should be practically municipalised—that is to say, the local corporations should include within their duties the very important one of seeing that the local medical charities are not allowed to suffer from lack of funds. It is impossible to doubt that were a local mayor to make the maintenance of the medical charities within his district a matter of prime concern during his term of office, immense good would The great drawback under which London hospitals suffer is that of the want of the organisation of local support. If the local medical charities in the various districts in London were supported, as they should be, by the residents, there would be but little need for the three cosmopolitan funds whose awards, when made, cannot, for several reasons, be regarded as unmixed blessings. In reflecting upon these matters one is at once reminded of the splendid manner with which the large medical charities in the provincial towns are maintained, among which may be mentioned the Royal Infirmary, Derby, the Leeds General Infirmary, and the Royal Infirmary, Newcastle. In these and other examples the local esprit de corps which prevails in favour of the medical charities leaves nothing to be desired. At the same time, however, this no doubt is largely the result of efficient organization, and, as such, it forms an instructive objectlesson to the residents in London who fail to do their part in the same direction. With the local London mayors, however, taking the lead in the organisation of the support of the London hospitals within their respective districts, the time should come when the financial position of many of these charities will cease to be a matter of deep concern. That which is accomplished so efficiently in the provinces, should not be a difficult matter in the metropolis, and we trust that the Municipal Corporation Act will be the means of ensuring that local support for London hospitals which is so essential in many ways to their well-

THE Turkish Government, in view of the approaching fêtes, has sent police officers to all the druggists' shops to seal up the packages of chlorate of potash, presumably with the object of checking the manufacture of explosives. The Turkish anarchist must, however, be lacking in resource if the deprivation of chlorate of potash prevented his carrying out whatever fell designs he may have conceived. In the matter of easily prepared explosives there is a positive embarras de richesse, and the puerility of this precaution is thereby rendered conspicuous.

The Indian Medical Association.

THE fourth annual meeting of the Indian Medical Association was held in Calcutta on December 23rd last, under the presidency of Dr. Lal Madhub Mookerjee. Rai Bahadur. The Association now numbers 1,151 practitioners of all grades, and is evidently flourishing. It was partly founded four years ago with the object of promoting necessary reforms, and of ameliorating existing grievances pertaining to the profession in India. The endeavours to obtain redress for the grievances of assistant surgeons and hospital assistants, both civil and military, have, we learn, so for succeeded that the Government have promised to make considerable concessions in the direction demanded. But there remain many other reforms, some evidently vital, which the Association are pledged to advance. Mention may be made of a few of them. One burning question is that of Government surgeons monopolising private practice. which mainly concerns, we presume, the native practitioners; another is the existence of irresponsible and unauthorised diploma-granting societies in India—clearly a most important matter. Another is the necessity for uniformity in higher education and in medical diplomas. All these are closely concerned with the welfare of the profession itself, and their importance is such that it is difficult to see how the Government of India can avoid giving them their serious consideration. Again, the Asso. ciation has pointed out that there is no Act regulating the sale of poisonous drugs, nor any system in vogue for State medical registration, and have urged the necessity of reform in both these particulars. Thus, judging from these evidences of official activity it is plain that the Indian Medical Association deserves well of the profession in India. Its programme of reforms deals with matters affecting the interests both of the profession as well as of the public, so much so that in this and other ways there appears to be a vast field of usefulness before it.

Methylene Blue as a Kidney Test.

FROM a clinical point of view it is clearly a matter of importance for the medical attendant to be able to estimate the permeability of the kidney. For that purpose two agents have been mainly used, namely. iodide of potassium and methylene blue. The experiments of Bard and Bonnet show that permeability is greatly diminished in all stages of intestinal nephri tis, whereas, in the parenchymatous form of the affection it is usually normal. Curiously, in interstitial nephritis secondary to epithelial involvement it is said that the permeability is diminished to the iodide salt, but is normal or increased to the The latter fact has a possible alternative test. or probable bearing upon the good effects of methylene blue in the generalised rheumatoid arthritis or, according to more modern nomenclature, chronic osteo-arthritis. The attention of the medical profession was, we believe, first drawn to this therapeutic procedure by Dr. J. R. Philpots, of Parkstone, whose original observation has since been borne out by many independent investigators.

There is still room for research in the matter of kidney stimulation and prima facie it would seem not unreasonable to ascribe remedial virtues to an agent that is visibly excreted even in cases of advanced renal damage where iodide of potassium fails to effect a passage. One explanation advanced is that the methylene blue acts as an organic or colloidal body and the other as a simple diffusible salt. That hypothesis, however, although good so far as it goes, nevertheless leaves a deal of the riddle unsolved.

The Progress of Harrogate.

THIS year Harrogate has the advantage of having a medical man as its mayor, and Dr. E. Solly who occupies that distinguished position has already proved the value of his appointment to the town. In 1897 the corporation opened a magnificent suite of baths costing practically £120,000, but in order to make the equipment complete it was subsequently decided to send a deputation to visit most of the spas on the Continent, and especially the kursaals, with the particular object of obtaining hints so as to enable the town to provide more facilities than at present exist for entertaining the visitors. As the result of the report of this deputation, on which Dr. Solly was the medical representative, steps are now being taken to prepare a scheme for erecting a magnificent concert hall on the model of the Continental kursaals. There can be no question that the policy thus being pursued by the mayor and corporation of Harrogate deserves every commendation, inasmuch as it is only by enterprise of this nature that the English spas will be able to successfully compete with those on the Continent.

Presentation to Mr. Alfred Cooper.

MR. ALFRED COOPER having reached the age limit according to the rules in force at St. Mark's Hospital for Diseases of the Rectum (City Road, London), has just retired from the post of senior surgeon to that institution. His connection with the staff of the charity has been a long one, having continued without interruption for thirty-four years. Under the circumstances, therefore, it was natural enough that he was not allowed to sever his active work with the institution without some recognition. Accordingly, on January 25th, he was presented at the house of Mr. Swinford Edwards with a Chippendale clock and silver cigarrette case, subscribed for by some members of the committee of the hospital, his colleagues, and old house surgeons. Upon the clock was a suitable inscription in commemoration of the occasion. Mr. Edwards, in making the presentation, alluded to the immense amount of human suffering which Mr. Cooper must have relieved during his long term of office, and also pointed out how much of the financial prosperity of the hospital had been due to Mr. Cooper's influence He further stated that Mr. Cooper's success and popularity were well known, the latter being largely due to his natural unselfishness, geniality, and sincere love for his fellow men. We understand that, in recognition of his services, it is

intended to appoint Mr. Cooper a consulting surgeon to the hospital.

The Transposition of Corpses.

FROM time to time the attention of the public is arrested by the gruesome tale of a confusion of corpses in the mortuary of some public institution. Now the report comes from the country and anon from the metropolis, but whatever its exact source the incident crops up every few months as surely as storm centres reach us from across the Atlantic or a labourer's wife presents her long-suffering spouse with a threefold addition to his family. The latest affair of the kind hails from the Southampton Workhouse, where two bodies of dead inmates were awaiting burial. The friends of one of the deceased, who lived in London, expressed their wish to have their relatives buried near their home, and sent the money to cover the necessary expenses. The workhouse officials thereupon promptly despatched to Lona coffin containing the wrong body. which was duly returned to them and the right corpse ultimately forwarded. All this points to a lack of the first simple principles of organisation and reflects most unfavourably on the institution where it is possible for such a scandalous mistake to be made. Is such a point as the management of the Poor-law mortuary, we wonder, beneath the notice of the all-knowing Local Government Board inspector? Arguing upon general grounds we may be tolerably certain that only a small proportion of such cases come to light. What becomes of the others? Yet when a person like Mrs. Druce brings forward good prima facie evidence of the possibility of a fraudulent burial, the law of Great Britain permits a thousand delays to be interposed, and the plain common-sense of opening the grave and seeing what is inside the coffin is adjourned sine die for months, or, perhaps, for years, to the great profit of the legal profession.

Small-Pox and Breach of Promise.

An interesting point was raised recently in the defence of an action for breach of promise of marriage brought against a miller's son in the Chelmsford Court. The defendant's mother, it appears, objected strongly to the proposed marriage, chiefly on the ground that the plaintiff had been rendered a "fright" by the ravages of small-pox. The consideration thus urged, however, failed to convince the jury, and a verdict of £25 damages was entered for the lady. In former days, when the disease mentioned was as common as diphtheria or measles nowadays, almost every other person one met in the streets was more or less deeply scarred and pitted with small-pox. Not a few instances are on record in which the disfigurement of the lady between the time of betrothal and that of marriage suggested grounds for the severance of the proposed contract. Whatever be the higher aspects of the case, there can be no doubt that there would be a fierce temptation to retire from the position for any but a man of the strongest moral calibre, if suddenly required to

marry a woman whose face had been transfigured from its former beauty into hideous repulsiveness. Thanks to Jenner and vaccination, this terrible human tragedy has in this generation disappeared However, now that the "strongest Government of modern times" has seen fit to do away with compulsory vaccination, it is quite possible that not a few of the present generation of medical practitioners will live to see many a fair woman in similar plight, on account of her marred beauty and ruined marriage prospects.

Lunatic Attendants and Corporal Punishment.

OF late, lunatic attendants have been unpleasantly in evidence as the administrators of unlawful punish. ment to the patients under their charge. weeks since a private asylum nurse was convicted in a London police-court for caning two of her charges. In the course of last week a ward attendant was fined 40s. for striking in the face a patient at the Peckham House Lunatic Asylum. With regard to this offence it may be remarked generally that in view of the modern humane spirit of lunatic treatment the resort to violence is an unjustifiable abomination, calculated to destroy all attempts in a curative direction. The life of an attendant upon insane patients is admittedly of a most trying nature, and one that demands the most perfect control of temper combined with tact and experience. For all that, it seems that the average attendant drifts into his position as does the average policeman. Both are turned loose into responsible positions without previous instruction, and left to pick up the necessary training knowledge according to their lights. During recent years it is true that a very commendable movement has been afoot to bring up the level of asylum nursing to modern standards, but a great deal vet remains to be done, especially in Poor-law institutions. Under any circumstances it would be well for all who undertake responsible duties as lunatic attendants to realise once and for all that under no circumstances are they justified in striking a patient. Otherwise they may find themselves in the uncomfortable predicament of the two defendants in the above-mentioned prosecution-not only damaged in pocket, but also cut adrift from their calling.

Medical Union.

THE prevalence of abuses in guise of medical charities and the present unsatisfactory financial situation of a large proportion of medical practitioners throughout the country are unquestionably due to the unfettered competition which characterises the struggle for existence within the pale of the profession. No progress can possibly be accomplished until medical men consent to forego petty rivalries, and join hands to impose reasonable conditions of remuneration. We note with pleasure here and there signs of a disposition to fall into line, of which the formation of a Medical Union among the medical practitioners of the County of Durham is an instance. The object of this Union is

association for the purpose to constitute an of considering all medico-ethical questions affecting the profession in the county and, in particular, to raise the contract price of sixpence per fortnight, which is the present usual contract rate between workmen patients and doctors in that part of England, to a minimum charge of ninepence per fortnight. We have been favoured with a copy of the rules which, though few in number, may well serve as a model for other similar combinations throughout the country. The new Union has our hearty sympathy, and this we shall be pleased to extend to all attempts to bring about that homogeneity of the profession without which no far-reaching improvement in material and social conditions is possible.

Before the Days of Jenner.

It is, of course, an impossible task to convince the anti-vaccinationist party of the error of their opinions, not even when appeal is made, as these faddists are always so fond of doing, to statistics. Still it is expedient that they should be, as often as possible, reminded of their folly. In this connection an interesting communication recently appeared in a morning newspaper respecting the various causes of death in a Yorkshire village one hundred and twenty years ago. From April 1777, as the parish Register showed, to April 1778, 122 burials took place, and the causes of death were as follows:—Apoplexy 1, dropsy 1, mortification 1, colic 1, sudden death 2, cancer 2, infants 5, consumption 9, old age (from 71-92) 12, fever 13, smallpox 55 (from the ages of 1-29). Thus in one year, no fewer than 45 per cent. of the deaths in this village alone were due to variola. For comparison's sake the author of these figures might, with advantage, make a further search of the parish Register, and publish the figures of recent years so far as they relate to the prevalence of small-pox.

Nicholson's Ear Drums.

The Newspaper Owner issues to the press a warning not to accept orders for the publication of the advertisements emanating from the person who calls himself Nicholson, unless they receive cash in advance. Our contemporary gives a roll of no less than fourteen aliases under which this person figures at different addresses from which he issues liberal advertising orders, but never—by any chance—pays if credit be given. One of these aliases was "the MEDICAL PRESS," which, however, he had to abandon when we threatened him with prosecution.

The Awards of the Prince of Wales's Fund.

A FORTNIGHT ago the editor of the Hospital replied to our remarks concerning the imperfections of the awards by the Prince of Wales's Hospital Fund, and he congratulates himself upon the fact that the distribution must have given general satisfaction, because the criticisms have been so few. In answer to this, it can only be said that he has probably found his way into that paradise which is not particularly associated with the presence of wise men. However,

his statements are for the most part too quibbling and puerile to call for serious criticism, and to adduce further arguments in support of our criticisms would be wearisome to our readers. Nevertheless in passing, we may remark that the matter has been claiming some attention in the lay press, and especially in the Daily News, as will be seen from a letter which we publish in our correspondence column. Whoever "Hospital Secretary" may be, it is evident that he is more than a match for the great Pandandrum of the hospital world.

Venereal Diseases in India.

A GENERAL order issued by the Commander-in-Chief in India provides for (1) the medical inspection of British soldiers serving in India for the purpose of detecting and checking the spread of contagious disease, and (2) for the enforcement of punishment for concealment of such disease. The inspection will be made from time to time without warning, groups of men being examined in whose case there is reasonable ground for suspecting that they are suffering from disease. The section of the Army Act providing for the punishment of men who attempt concealment is to be rigidly enforced.

Mortality of Russian Troops at Port Arthur

THERE is now little room for doubt that the mor tality among the Russian troops at Port Arthur is of a very serious nature. The cause is said to be the impurity of the drinking water, but a medical Commission has been appointed to make a special investigation into all the circumstances of the case. The high death-rate has been maintained since November last.

Dr. F. J. Waldo, Medical Officer of Health for the Temple and St. George's, Southwark, has been appointed to the Milroy Lectureship for 1900 by the Royal College of Physicians of London. The subject selected is "Summer Diarrhea, with Special Relation to Causation and Prevention."

THE President and Vice-Presidents of the Royal College of Surgeons of England will entertain the Lord Chief Justice (Lord Russell of Killowen) at dinner on Tuesday, February 14th.

DR. WALDO, Medical Officer of Health for St. George's, Southwark, has stated that about one in every 14 of the population of his district is born, brought up, lives, and dies within the four walls of a one-room tenement.

DR. VALLANCE, Medical Officer to the West Ham Union, on Monday last, obtained a verdict with £150 damages against a meat salesman for slander.

In the parish of Darrington, on Salisbury Plain, consisting of nearly four hundred inhabitants, no death occurred during last year.

DR. BEIDGWATER has resigned the chairmanship of

the Medical Charities Committee of the British Medical

Mr. WILLIAM TAYLOR, F.R.C.S.I., has been appointed Visiting Surgeon to Cork Street Fever Hospital, Dublin, in room of Prof. Wm. Stoker, F.R.C.S.I., whose term of office expires on the 31st proximo.

MR. F. T. HEUSTON, F.R.C.S.I., President-elect of the Dublin branch of the British Medical Association, will deliver an address at the annual meeting of the branch on February 6th, entitled "The Position of the Poorlaw Medical Officers in Ireland."

COLONEL ROONEY, F.R.C S.I., Commander Royal Army Medical Corps, Scotland; Captain D. Hepburn, and Captain W. Bashford, of the Edinburgh Company of the Volunteer Medical Staff Corps, have each received from the Royal Red Cross National Society of Spain a diploma in recognition of services rendered to the Society.

Correspondence

We do not hold ourselves responsible for the opinions of our

THE PRINCE OF WALES'S HOSPITAL FUND.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-Those of your readers who have followed the incidents associated with the distribution of this Fund cannot but be interested in the correspondence which has recently occupied the columns of the Daily News and Daily Chronicle, in which "A Hospital Secretary" has complained of the inadequate grants to various hospitals loaded with an undertaking to open further beds as well as to others, on condition of effecting structural and other alterations, which would more than absorb the amount of the awards.

Another writer, bearing the same signature but apparently a different correspondent, has, in the Charity Record, taken much the same line as you have, viz, that exceptionally handsome grants have been given to hospitals already, although possibly insufficiently, endowed, while many small hospitals have been altogether excluded.

Comment has further been made on the great partiality shown in the grants to hospitals, even of the same class and claims, as, for instance, the awarding £1,000 to one Chest Hospital, while another, which receives an equal grant from the Metropolitan Hospital Sunday

Fund, is awarded only £100 from the Prince of Wales s.

The incident which has led to the closure of the discussion in the above-mentioned journals is characthe data in the unfairness of those responsible for the administration of this Fund. The sub-Editor of "Burdett's Hospitals and Charities," writing to the Daily News, accused "A Hospital Secretary" of a mis-statement of fact in saying that the figures supporting his argument were derived from the columns of that publication. This accusation was repeated in *The Hospital* of last week. "A Hospital Secretary' answered this apparently damaging charge by stating that he had arrived at his figures by simply multiplying the tables given in "Burdett's Hospitals and Charities" which show the cost per day by the number of days in the year. But beyond this, as a matter of fact, the cost per annum is also to be found in other parts of this publication, and are found to be really in excess of that calculated by "A Hospital Secretary."

The current number of The Hospital allows the accusation to go by default, for not only is there no withdrawal of the charge, but the matter is not further mentioned, nor has there appeared any acknowledgment of the error in the paper in which the accusation first appeared.

I am Sir, yours truly, A HOSPITAL SURGEON. "UNCHRISTIAN CHARITY."

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,—My attention has been drawn to the leading article in your issue of January 11th, entitled "Unchristian Charity." While entirely agreeing with the views you have put forward, yet in the spirit of fair play and justice, I must take exception to one statement, which, if allowed to go unchallenged, might reflect injuriously on the charitable institutions of Dublin. I find the following statement in reference to unmarried women who are pregnant, "In some lying-in hospitals they are altogether placed under a ban, and even the more liberal only concede accommodation at a first confinement." In Dublin we have three well managed lyingin hospitals, and I believe I am right when I state that no such exclusion is practised. Of one of them—the Coombe—I can speak with authority, and in this case the only recommendation required to gain admission day or night is the fact of the applicant "being in labour."

I am, Sir, yours truly,

FRED. WM. KIDD.

17 Lower Fitzwilliam Street, Dublin, January 23rd, 1899.

Obituary.

SIR JOHN NUGENT, M.B., T.C.D.

THE death is announced, at the great age of 94, of Sir John Nugent, who for nearly half a century held, practically, complete control of the Irish Lunacy Service. He received his appointment, as Inspector of Asylums, about the year 1845, having been forced upon the Government—which desired to give the place to another—by Dan O'Connell, then in the zenith of his power, whose body-physician Nugent then was. At that time, and until quite recently, the two inspectors were, in fact, the Irish Lunacy Department, and the "Board of Control," the Castle supervision exercising only nominal restrictions on their action. Nugent was a very remarkable man. Full of brains, with the determination and persistence of a bull-dog, he was a thorough autocrat, and not being throughout life at all particular about the means he adopted to carry his ends, he, within a short period after his appointment as inspector, swept out of his way everyone in the department who seemed likely to have a will of his own, and made himself, practically, the dictator. Thus he became known as one of the two "Kings of Brentford" in Ireland, the other being Sir Alfred Power, who had established himself in the same regal authority on the Irish Local Government Board. Needless to say that the exercise of this domination produced many conflicts with the Boards of Governors and resident physicians of asylums. On one occasion he tried to snub the Limerick Board, forgetting that among its members was the Hon. Spring Rice, afterwards Lord Montague, who was in close official relation with the Government, and who at once resigned his governorship and was followed by many of the leading members, and in the end Nugent sustained a heavy fall. On another occasion his removal from office was nearly brought about by his using the cloak of his authority to protect an incompetent and negligent President-Superintendent, who had permitted one of the Asylum inmates to be drowned in a bath by two of the attendants. Upon the representation of some of the Governors, the sham investigation held by Nugent was reopened, the President was dismissed, the attendants were criminally prosecuted, and Nugent barely escaped dismissal. To the last his courage never deserted him. When, at a great age, it was suggested to him that he should go out on a pension, he absolutely refused to move unless he got his full salary, and, being fortified by the uncertainty of the law, held on unguis et dentibus until the Treasury gave in.

Sir John Nugent was a man to be feared and admired for his extraordinary individuality. He was a brilliant conversationalist, and a pleasant man to meet at dinner. As to his other characteristics, there are many past 128

officers of the Lunacy Department in Ireland who could say a great deal which we are not disposed to say. the time of his death, Sir John Nugent was staying at the St. George's Club, London, under the care of Dr. Mapother.

PROF. COATS, M.D., OF GLASGOW.

THE death of this distinguished pathologist, although in the prime of life, was not unexpected, but Glasgow mourns her loss nevertheless with unfeigned regret. Our columns previously chronicled the fact that about a year ago Dr. Coats was compelled on account of a dangerous illness to relinquish his Chair of Pathology for a time for residence abroad. He subsequently took a voyage round the world, but the malignant internal disease continued to make progress, and although he resumed for a time his post of Professor in the University, a few weeks since this had to be finally given up, and death came to release him after intense suffering on Wednesday last From the time he took his M.D. degree, in 1870, he was engaged in the work of teaching, and was for a number of years pathologist to the Glasgow Royal Infirmary. On the completion of the Western Infirmary he was appointed pathologist in that institution, his lectures being recognised by the University authorities and by the Faculty. In the year 1890 he became Lecturer on Pathology in the University, and three years later a Chair of Pathology was founded in Glasgow University, to which with unanimous consent of the Senate, and to the special satisfaction of the members of the Faculty, Dr. Coats was appointed its first occupant. As a teacher Professor Coats was earnest and painstaking; he was held in the highest esteem by the long succession of students who passed through his classes, and it may be truthfully averred that few Scotch students of the last decade did not take his "Manual of Pathology" as their guide on the subject. He was a frequent contributor to the medical journals, and was for some time editor of the Glasgow Medical Journal. He died at the early age of fifty-two, regretted by a wide circle of friends.

Literature.

GANT'S GUIDE TO THE EXAMINATIONS BY THE CONJOINT BOARD. (a)

THE seventh edition of our old friend "Gant's Guide to Examinations," duly brought up to date by Dr. Willmott Evans, will, doubtless, continue to stimulate the anxious curiosity of students who covet the diploma of the Conjoint Board of England. An honourable and successful career extending over upwards of sixty years is a great tribute to the author's sense of fitness, and really no student can well afford to be without his guide to the Examinations. Extensive changes have been introduced into the curricula since the last edition, but the size of the book appears not to have been increased pari passu with the extension of the period of study. This result has been attained by the omission of many of the older Examination papers, which would not assist the student in preparing for the present examinations. The book is at once a handy guide and a friendly adviser, and we can imagine no better means of furbishing up one's knowledge on the eve of an examination than by carefully running over the appropriate chapters. Dr. Evans's share of the work leaves nothing to be desired.

TOBIN'S SYNOPSIS OF SURGERY. (b)

This small book is marvel of cheapness and excellence from the publisher's point of view. It is printed partly in new and partly in old type, on gilt-edged paper, and is interleaved so as to permit of complementary notes, while the binding is in limp morocco. In spite of all this

luxury it only costs six shillings and sixpence. Having said this much for the publisher it may not be out of place to discuss the merits of the text. This virtually consists of a synopsis of the author's lectures, being in fact the heading was a least to be a least t fact the headings used by him for his clinical demonstrations. There is a preface, followed by fifteen pages of introductory remarks which seem rather out of place in a cram-book. The notes are fairly comprehensive, and though not always "up to date" are sufficiently complete for general purposes. We note the absence of familiar terms such as coxalgia, cora vara, and the like, and the author uses tubercular and tuberculous as exchangeable terms, though the latter is the appropriate one when speaking of tuberculosis. Mention is made of a disease called "rhino-scleroma," but no reference to it is contained in the index, though as it is unknown outside Austria this is no great loss. Hydrophobia again is indexed as "rabies" and on a wrong page. In the brief remarks on actinomycosis no mention is made of the specific, iodide of potassium. We might point out many other like omissions, but as the book is interleaved the student can fill up any lapsus as he goes along.

RIDEAL'S "DISINFECTION AND DISIN-FECTANTS." (a)

This work deals with the difficult subject of disinfection with a completeness never before attempted, and will be especially valuable to those on whom the responsibility falls of purchasing large quantities of disinfectants for the use of public bodies, who up to now have been practically without any work from which they could obtain information on the ever-increasing multitude of substances that are offered for sale as disinfectants, some of them possessing a very slender title to the claims made for them.

The book is divided into fifteen chapters and sundry appendices. The first chapter is introductory, the second deals with mechanical disinfection, then follows disinfection by heat, chemical disinfection, two chapters each being assigned to the non-metallic compounds and metallic salts. The various organic substances are dealt with in the four following chapters. After this the practical applications of disinfectants are ably set forth. Chapter XIII. is devoted to disinfection as applied to the body, and to the consideration of food preservatives.

Legal statutes and regulations are discussed in Chapter XIV., and the last chapter is occupied with the methods best suited for the valuation of disinfectants. It is this chapter that we should wish to see amplified. because the author's experience is such that his observations would have great weight, and be of practical value to many who have attempted experimental estimations of this nature. Many accounts of experiments as to the relative value of the best known disinfectants have been inserted, and the author has exercised a careful discrimination in including only such as are trustworthy. a reference work on disinfection the book is unique, and should be in the library of every sanitarian.

DIBDIN'S PURIFICATION OF SEWAGE AND WATER. (b)

This work must be reckoned as one of the greatest practical importance to all engaged in the disposal of sewage. It is undoubtedly due to the efforts of the author that the old and erroneous notions of sewage disposal are being discarded and commonsense methods adopted in their stead. In this second edition now before us, Mr. Dibdin has corrected certain minor errors inseparable from a first edition, and has added much useful information as to the interpretation of analytical results in sewage analysis, more particularly in the case of certain variations in the amount of saline and albumenoid ammonia found in a particular sewage by different observers. The chief novelty in the book is, however, a number of figures relating to the effects produced by the application of the bacterial system of

(a) "Disinfection and Disinfectants." By Samuel Rideal, D. C. (London). F.I.C., &c. Second edition. Price 12s, 6d. London: The Sanitary Publishing Company, Limited.
(b) "The Purification of Sewage and Water." By W. J. Dibdin, F.I.C., F.C.S., &c. Second edition, revised and enlarged. Price 21s. London: The Sanitary Publishing Company, Limited.

⁽a) "Gant's Guide to the Examinations by the Conjoint Board in England and for the Diploma of F.R.C.S.," with Examination Papers. Seventh edition. Price 5s. Revised throughout by W. H. Evans, M.D., B.S., B.Sc. Lond., F.R.C.S. London: Bailliere, Tindall, and Cox. 1899. Price 5s.

(b) "A Synopsis of Surgery." By R. F. Tobin, F.R.C.S.I. London: J. and A. Churchill, Price 6s, 6d,

sewage treatment to sewages of widely differing characters, some being of a purely domestic nature, while others contained trade effluents of almost every conceivable description. So good is this information that it is alone sufficient to induce all who possess a copy of the first edition to invest in a copy of the present one.

There is but one point on which we should like to have seen a clearer expression of opinion by Mr. Dibdin, because from his unique experience he is highly qualified to take a correct view of the whole aspect of the problem. The point we refer to is, how far can anything in the nature of standards of purification come into practical use; or, putting the question in another form, what is the percentage degree of purification that a successful process should effect? It may be that no definite answer can at present be given to these vital questions, but it is to be hoped that in the near future a direct answer may be formulated.

THE SOUTH AFRICAN CLIMATE. (a)

The book commences with a letter from Mr. Cecil J. Rhodes—the great Empire builder, who has given his name to so much of the Continent. He tells us that he induced the De Beers Company to spend £20,000 in erecting a sanatorium near Kimberley, and he mentions that "Our Plateau has the advantage over St. Moritz and other places on the Continent (of Burope) of having a dry warm climate, free from mist and cloud; and, in addition, you are not exposed to the chills which naturally occur in the shade at similar altitudes in Europe"

ally occur in the shade at similar altitudes in Europe."

The book consists of fifty-eight pages of letterpress and an appendix of about one hundred and fifty pages. The appendix is the essential part of the book, and is made up of a series of eleven articles contributed by a corresponding number of medical writers, whose names

are attached to their contributions.

We think Dr. W. C. Scholtz would be more fittingly described as the editor of the book; for his share in the authorship is not easily recognised. The book is, however, a useful addition to our knowledge of South Africa as a health resort.

Medical Aews.

Royal College of Surgeons of England—Lecture Arrangements.

An announcement will be found in our advertisement columns of the forthcoming lectures to be delivered at the college between now and Easter. Professor Leonard Hill will commence a course of three lectures on "Researches on the Influence of Gravity on the Circulation" on Feb. 6th. Dr. T. G. Brodie will deliver three lectures on "The Chemical Pathology of Some Infective Diseases," commencing on Monday, Feb. 20th Mr. B. G. A. Moyniham will deliver three lectures on "The Anatomy and Surgery of the Peritoneal Fosse," commencing on Monday, Feb. 27th. Professor F. G. Parsons will deliver three lectures on "Joints of Mammals, contrasted with those of Man," commencing on Monday, March 6th. And Professor Charles Stewart will deliver six lectures on "Alternation of Generation and Recent Additions to the Museum," commencing on Monday, March 13th. The lectures will be delivered at 5 o'clock p.m. each day. Fellows and members of the College are invited to attend; other members of the profession will be admitted free on presenting their private visiting cards.

Vital Statistics.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 18.2 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of the year 1898.

Birkenhead 16, Birmingham 18, Blackburn 20, Bolton 21, Bradford 19, Brighton 17, Bristol 18, Burnley 13, Cardiff 15, Croydon 15, Derby 13, Dublin 28, Edinburgh 20, Glasgow 22, Gateshead 23, Halifax 22, Huddersfield 17, Hull 20, Leeds 16, Leicester 14, Liverpool 21, London 17, Manchester 21, Newcastle-on-Tyne 19, Norwich 21, Nottingham 19, Oldham 15, Plymouth 16, Portsmouth 17, Preston 22, Salford 16, Sheffield 18, Sunderland 21, Swansea 26, West Ham 15, Wolverhampton 20. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 2'2 in Nottingham and 2'4 in Gateshead; from whooping-cough, 1'7 in Nottingham, and 1'8 in Birkenhead; and from "fever," 1'3 in Bolton and in Preston, and 1'8 in Burnley. In none of the large towns did the death-rate from scarlet fever or from diarrhosa reach 1'0 per 1,000. The 72 deaths from diphtheria included 30 in London, 5 in Liverpool, 4 in West Ham, 4 in Portsmouth, 4 in Leicester, 4 in Sheffield, 3 in Birmingham, and 3 in Leeds. No death from small-pox was registered in any part of the United Kingdom.

Tribute to a Medical Editor.

The Board of Trustees of the American Medical Association recently passed the following resolutions on the death of the editor of their Journal:—Whereas, in the wisdom of Divine Providence our worthy secretary and editor, Dr. John B. Hamilton, a loyal friend, a devout Christian, a great man, has in the prime of his manhood been called from his earthly labours to eternal rest, therefore, be it resolved, That the trustees of the American Medical Association desire to express their deep appreciation of a faithful servant, one whose untiring energies in the interests of their Journal have received the recognition of the medical profession of the world. Resolved, That while his business capacity has been exemplified in all the undertakings of his life, and success had crowned his every effort, notably as a sanitarian, a surgeon, and a surgical teacher, yet, above all, the position to which the Journal of the American Medical Association has attained through his efforts marked him as being possessed of superior executive ability and rare editorial genius.

"Why weep for him? For him the angels came;
Ere yet his eye with age grew dim, or bent the stalwart frame;
His weapons still were bright, his shield was lifted high
To slay the wrong, to save the right—what happier time to die?"

E. E. MONTGOMERY JOSEPH EASTMAN Committee. H. L. E. JOHNSTON

The Mortality of Poreign Cities.

The following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Calcutta 29, Bombay 54, Madras —, Paris 19, Brussels 18, Amsterdam 18, Rotterdam 17, The Hague 18, Copenhagen 19, Stockholm 20, Christiana 18, St. Petersburg 30, Moscow 28, Berlin 16, Hamburg 17, Dresden 19, Breslau 24, Munich —, Vienna 21, Prague 28, Buda Pesth 24, Trieste 33, Rome 22, Turin (10 days) —, Venice —, Cairo —, Alexandria —, New York (including Brooklyn 23, Philadelphia 27.

West London Medico-Chirurgical Society.

At the meeting of this Society next Friday, February 3rd, there will be a discussion on "The Treatment—Medical and Surgical—of Acute Inflammation of the Vermiform Appendix." The annual dinner of the Society will he held on Wednesday, February 8th, at the Trocadero Restauran, Piccadilly, at 7 for 7:30 p.m. The President, Dr. S. D. Clippindale, will preside. Prof. William Osler, F.R.S., of Baltimore, who has accepted the Cavendish Lecture-ship for 1899, who would have been the chief guest at the annual dinner, will be unable to be present.

At a meeting of the trustees of the John Lucas Walker Studentship in Pathology, held on January 27th, 1899, W. Myers M.A.M.B., B.C.Cantab., B.Sc Lond., was elected Senior Student, and E. Sydney St. B. Sladen, M.A., M.D.Cantab., was elected Junior S udent. Dr. Myers is working under Professor Ziegler at Freiburg; Dr. Sladen is working at the Cambridge Laboratory.

WANTED, THE CONSIGNOR.

MESSRS. BURROUGHS, WELLCOME AND CO. inform us that they recently veceived from Sydney a large packet of herbs which was put on board the "Thermopylae." No advice was received in reference to it, and it is not known from whom the parcel came. An attempt ha been made to identify the plants, but it has not proved successful. It is probable that they were dispatched to them for identification and investigation by a medical man or chemist who intended to write at the same time, but failed to do so. Should this meet the eye of the consignor he is requested to communicate with them.

D. P. H.- The Local Government Board have intimated that they have no intention at present of favouring the suggestion to make tuberculosis a notifiable disease.

AN UP-TO-DATE CONSCIENTIOUS OBJECTOR.

THERE were several applicants to Mr. Plowden, at Maylebone Police Court last week, for certificates of exemption from vaccination. One applicant gave as his reason for objecting to the operation that if small pox was to come it would come; vaccination would neither stop it coming nor diminish the risk, and the introduction of the "animal lump" into the child's system would do no

duction of the "animal lump" into the child's system would do no good.

Mr. Plowden: Animal what?

Applicant: Animal lump -1-u-m-p h. (Great laughter.)

Mr. Plowden: After that I really think I must refer you back to a little more extensive reading. No lumps whatever are introduced. You talk of the child as if it were a pudding. (Laughter.)

Baris Clinical Lectures.

THE TREATMENT OF ACUTE INTESTINAL OBSTRUCTION.

Delivered at the Hôpital de la Pitié, Paris,

By Professor P. BERGER, Professor of Clinical Surgery.

(Concluded.)

It is evident that the mode of intervention in cases of intestinal obstruction must entirely depend upon the nature of the obstacle. Here, as elsewhere, a correct diagnosis leads naturally to correct treat-

ment; but, you may ask, is a correct diagnosis of the cause and the nature of the malady possible?

Some of my colleagues display in this regard a want of confidence which I do not altogether share. There occur, certainly, cases in which we are left in the most complete obscurity; others there are which falsify every prediction; but often, also, a careful scrutiny of all actual phenomena, a close investigation of all the circumstances preceding or accompanying their appearance, enable the observer to arrive at a trustworthy conclusion, or at least to presumptions upon which he may base his decision, and make choice of one or other operative alternative, in accordance with fixed rules. The following is my advice for carrying out the examination, and deciding according to the result upon this or that surgical intervention.

In presence of symptoms of acute obstruction supervening in a patient previously in good health, our first consideration must be the possibility of the symptoms being due to conditions more or less analogous but quite different in their nature, particularly subacute peritonitis due to perforation or appendicitis. The amount of fever in some cases, the pulse and temperature in others, the rapid change in the appearance of the face, the loss of heat in the extremities and extremities the capitality of the cap extremities and extreme anxiety, the sensibility of the belly to pressure and even to the slightest con-tact, the different character of the pain due to spasmodic contraction of the bowels, and in strangulation, suffice very often to establish a diagnosis. In the rare cases, in which doubt may exist, laparotomy will enable us to clear it up with the least possible delay. But let us suppose the diagnosis of acute obstruction to have been established with certainty, in every patient, whatever his age and general condition, the first care should be the search for local signs. These may be revealed by careful examination of the abdomen. This sign may be pain fixed always in the same spot; a sensation of more marked resistence in one spot; a local distension, or, on the contrary, a vague or more pronounced sensation of a deep tumefaction; or periodical attacks of pain and constriction of the intestine making themselves felt always in the same spot. Whatever sign be found, the most careful note should be made of it. In examination the greatest care should be particularly directed to the regions where the more deeply seated hernise occur; not only the deeper regions of the groin, but the semi-lunar line of Spigel; the para-umbilical region, that of the adductors, even

the sciatic notch itself should be examined by palpation. Examination per rectum and per vaginam should be carried out with the utmost care, and it should be borne in mind that by this method, and especially per vaginam, the greatest number of obturator herniæ have been recognised. With this method of examination we must combine also deep palpation of the hypogastric and inguinal regions. During the vaginal examination the exact condition of the organs of generation and their appendages must not be overlooked, and this remark applies equally to Douglas's pouch, where elytroceles may be strangulated.

If a local sign be found showing certainly or probably that a lesion exists in a determined spot in the abdomen, no hesitation is allowable. If the general condition of the patient permit, it is imperative to go straight to the spot where the pain has been localised or the deep swelling discovered, either by direct incision over the spot or by median laparotomy to proceed to the sensitive spot or towards the deep swelling which has been discovered. The incision will be above or below the umbilicus, according to the position of the local sign, and the hand introduced should be directed towards the suspected locality. The lesion having been discovered—tumour. invagination, torsion, mass of intestine fixed by adhesions, or caught in an orifice or nipped by a band, or other morbid condition-must be dealt with according to rule. All necessary space must be given by enlargement of the first incision, so as to avoid unnecessarily complicating the operation. Extremely careful examination will often reveal a sign to guide exploration. Of six cases of volvulus of the iliac flexure Heidenhain was able to diagnose four, in four out of six cases of internal strangulation, and in three out of seven cases of twisting of the small intestine

which called for laparotomy.

But failure is possible. If the examination reveal nothing which sheds light on the nature of the real cause of symptoms, it is only the eye, the general state of the patient, and the length of time that has elapsed since the beginning of the symptoms, which can

guide us to a decision.

In a young and healthy subject who has been suddenly seized, without warning, with symptoms of acute obstruction, the probabilities point to an internal strangulation of one kind or another, or to torsion, unless the case be one of pseudo-paralytic strangula-tion, impossible to diagnose except by treatment. If the patient's strength permit, and if the symptoms are not of too long duration, after having tried an electrical injection on the method laid down by Boudet, recourse should be had without delay to laparotomy.

If the patient be advanced in years we must first eliminate cancer of the bowel, unless it be merely a case of obstruction due to fæcal accumulation. Torsion, invagination, and compression by tumour, may equally be met with. In a certain number of these cases, examination of the shape of the belly and of its sonority as showing that the large intestine is involved partly or totally in the distension of the digestive tube will suggest the choice of operation. It is to an artificial anus in the left iliac region that we must have resourse if we are sure that the obstacle is seated at the termination of the iliac flexure. If doubt exist, the operation must be done on the right side, since it is important to reach the large intestine at a point above the obstacle, or failing that, at the last folds of the small intestine. An electrical injection will have been first administered if the condition of the patient allow of it.

In intermediate cases, in patients of middle age, where no local symptom and no history throws light on the probable seat and character of the obstruction, it is the general condition of the patient, and the time during which symptoms have existed which must govern intervention. The facial expression, the pulse, the body heat, and the greater or less distension of the belly will be noted. The presence of bacterium coli in the urine, in the blood, may furnish a contraindication, but time for such investigation may not be available. Albumen in the urine may be more easily recognised. Pulmonary complications and congestions depending upon intestinal septicæmia must not be overlooked. When the result of the examination is favourable and shows the patient's condition to be fairly good, it is to laparotomy that recourse should be had. And here two modes of operating, two opposed practices, have to be considered.

A long incision of the abdominal wall may be practised so as to expose the whole of the viscera and to facilitate discovery of the obstacle; but when the bowels are much distended, such an incision at once exposes the whole mass of intestines, and although these may be surrounded by sterilised compresses, prolonged exposure of a large portion of bowel constitutes a danger in itself. Moreover, great difficulties and complications arise when the protruding mass of bowel has to be returned and the abdominal incision closed by suture. In order to accomplish this it is often necessary to evacuate the contents of the intestine through a small incision into one of the folds of bowel—an incision afterwards closed by suture. But evacuation of the distended intestines in this way gives rise to danger of infection through the bowel as well as by the abdominal cavity. Although many surgeons adopt this practice, and although Helferedi claims nine successes out of thirteen cases by it, we should not adopt it as a general rule.

In ordinary cases I think it is better to make an incision permitting direct inspection in a certain locality and introduction of the hand. The cæcum can thus be examined, and if distended can be followed from end to end seeking for an obstacle in the transverse colon and the iliac flexure. Failing to discover rapidly the cause of obstruction it is better at once to perform artificial anus under conditions which are very favourable to a cure.

If the excum be empty there ought to be no difficulty in discovering close at hand the lower end of the small intestine, and this can be followed to the obstacle. Or the following method, Heidenhain's, may be employed:—The incision being made, the first coil of intestine which presents itself is allowed to escape, and this usually proves to be one of the folds close to the obstacle. This is traced back towards the end fixed by the obstacle.

In whatever way the examination is carried out it ought to be done as rapidly as possible: and it is always better to make an artificial anus than to expose the endurance of the patient to too prolonged a strain. But if it is perceived that the mass of the small intestine twisted upon itself constitutes the greater portion of it; if it is evident that the obstacle is in the higher parts of the digestive tract, it is justifiable to enlarge the original incision in order to allow the necessary length of bowel to be drawn out and to permit of an opening being made in the proper situation to void their contents and diminish their

volume. It is here that the procedure recommended by Helferich and Kümmell becomes applicable.

As just laid down, except in cases where exceptional indications present themselves, complicated operations ought to be avoided—entero-anastomoses as well as intestinal resections and enterorrhaphies with Murphy's button. To prove successful, laparotomy requires to be done in the shortest possible time.

Whatever the age of the patient, if the case present

Whatever the age of the patient. if the case present symptoms of advanced strangulation, reliance must mostly be placed on Nélaton's enterotomy practised in the iliac fossa or in the right flank, or in the first fold of intestine which presents itself through the incision.

Except in extreme cases it must be borne in mind that laparotomy may end in artificial anus, and it must not be forgotten that during the former operation something may occur to make evident the nature of the obstacle and permit of its removal. It therefore seems desirable always to make an incision large enough to permit the entry of several fingers, if not of the whole hand, for the purpose of exploring the whole abdominal region.

Examination of the patient, diagnosis and interference may be summed up thus: — Laparotomy, exploration and removal of obstacle constitute the rational and truly surgical method. Preference should be given to this method according to the girth of patient, recent strangulation and good general condition and guidance of local signs. In aged patients, and especially when the large intestine participates in the distension, cancer must always be suspected, and it is to artificial anus that recourse must often be had in such cases.

It must never be forgotten that pseudo-paralytic strangulations and spasmodic strangulations, cases in which there exists a functional obstacle, are common, and that they can often not be distinguished by clinical examination from cases of mechanical obstruction. When the patient's strength permits, therefore, we ought always to practise electrisation of the bowels very carefully and methodically before surgical interference is attempted.

The cause of failure in the treatment of intestinal occlusion is due mainly to faulty diagnosis. Once thoroughly convinced of this fact the necessity for the most careful and exhaustive examination in the cases needs no insistance. Interference must be always directed by the special circumstances of individual cases. It is to clinical observation that we must look to remove the obscurity which now surrounds the diagnosis in many cases of acute intestinal obstruction, and to establish on a more secure foundation the rules of treatment by operation, the results of which, so far, show very little improvement, in spite of the progress effected in operative technique.

NOTES ON THE

OXYGEN TREATMENT OF WOUNDS. By GEORGE STOKER, M.R.C.P.I., M.R.C.S.Eng.,

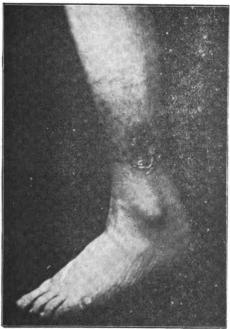

Physician to the London Throat Hospital.

It has always been believed that the oxygen treatment brought about healing as the result of some process of oxidation affecting either the food on which the micro-organisms live or their excretions or toxins. This being so it is necessary that the oxygen used should be of the highest standard and free from all impurities.

Oxygen from various sources has been tried, and undoubtedly the purest and of the highest standard is that prepared by Brin's Oxygen Company, containing, as it does, not less than 96 per cent. of pure oxygen.

Attention has been directed to the effect of this

treatment in producing toxic reactions in a large number of cases, which has led to the belief that oxygen affects most of all the excretions of the microorganisms, changing them into anti-toxins by oxidation. (Vide Lancet, December 10th, 1898.) This change has been most marked in the case of the bacillus pyocyaneus which is found by experience

CASE I. Photo No. 1.

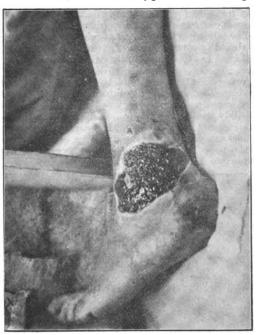

to be the most persisting and most inimical to healing of any of the micro-organisms usually found in wounds.

Case 1 Photo No. 2.

If a sterile broth be prepared, and a stream of exygen passed through it, no result is apparent. If this same broth be inoculated with the bacillus this same broth be inoculated with the bacillus pyocyaneus and incubated for 14 days, in an air-tight for several hours the deep green colour becomes perflask, and then oxidised as above indicated, two manent. This last observation, confirms the necessity immediate results are observed.

1. It at once turns a vivid green colour, which deepens and intensifies as the process of oxidation is continued, and (2) from being liquid, the fluid becomes thick and glutinous or almost semi-gela-tinous. These results indicate (1) that the bacillus pyocyaneus has profoundly altered the character of the broth, and (2) that the oxygen has further pro-

CASE II. Photo No. 1.

foundly modified the character of the broth so altered. This product of oxidation is volatile; for if the stream of oxygen! is discontinued after a few minutes,

CASE II. Photo No. 2.

the broth will, in the course of an hour or two. resume for the continuous exposure of the parts affected to

oxygen gas, in order that this treatment may be

effectually carried out.

It is believed by many that the oxygen treatment is only useful in cases of chronic ulcers and scres, this is a grave misapprehension, the most brilliant results are seen when the treatment is used in cases of recent wounds, burns, &c., both in reference to the rapidity of healing as well as to the nature of the new skin formed; for it is not any ordinary cicatrix that is produced, but a skin almost physiologically perfect.
The following are quoted as showing the results
produced in several kinds of cases:—

Case I.—Chronic Senile Gangrenous Ulcer.— Mrs. T., et. 83, about three weeks previous to entering the Oxygen Home, the patient got a bruise on the shin, and an ulcer formed which extended very rapidly, became very offensive, and was exquisitely tender and painful. On admission the ulcer was covered with a hard, dry, darkish green scab, almost exactly like what one sees in senile gangrene of the toes. A few days after the oxygen treatment was begun a healthy action was set up, and the ulcer

CASE III. Photo No. 1.

was completely healed in eight weeks. This was by no means a rapid case of healing as compared with others, but considering the serious nature of the complaint and the great age of the patient (83 years) I regard it as one of the most remarkable cures we

have effected.

CASE II .- Recent Wound .- J. M., &t. 47. Three weeks before admission the patient was knocked down by a heavy van, the wheel passing over the outer side of the left ankle, which was badly bruised, the bruise eventually sloughed off leaving a large open wound (vide Photo 1., Case 1I.) both extensive and deep. The patient was under treatment for twelve weeks. For the first four or five weeks the wound healed rapidly and then remained stationary for two or three weeks. On July 12th, he got a reaction, the tempera ure rising to 103 degs F., with quick pulse, but very little general malaise. The wound remained moist, and healthy, and painless. There was, however, some pain and swelling in the lymphatics extending up to the groin. The reaction lasted three days during which time and after the wound healed rapidly and the patient was discharged cured on August 12th (vide photo No. 2, Case II).

CASE III.—Lupus of Face and Ear.—H. T.—, set. 29. This girl had been afflicted with true lupus of her face and ear for 14 years. The disease first showed itself on the side of the nose and gradually spread till it engaged all those parts shown in Photo 1, Case III.

A great variety of treatments had been tried. Her face had been scraped (under an anæsthetic) four or five times before she came into the Oxygen Home. Various lotions, continents, and caustics had been tried but to no purpose, and in the two years previous the disease had spread rapidly.

The treatment began on November 9th, the diseased surface being carefully scraped and filed, and oxygen applied, as soon as the bleeding ceased, by means of

a gutta-percha mask.

As the diseased surface was so extensive, it was found impossible to enclose it all in one apparatus, and so reveral scrapings were necessary. An oxidised toxin was prepared from cultivations taken from the wound, and when used produced several reactions, and indicated several outlying areas of infection.

CASE III. Photo No. 2.

The patient was under treatment for twelve months, this lengthened period being necessitated by the fact that one part had to be completely healed before the

adjoining portions could be scraped.

The points suggested in using this treatment in such cases as this are:-

1. To remove the diseased surface by scraping. 2. The skin grown under oxygen being almost physiologically perfect is more capable of resisting further pathological attacks than an ordinary

cicatrix. 3. The formation of oxidised toxins on the wound itself, and the use of those artificially prepared, not only assist the healing, but also attack outlying lupoid areas, causing them first to break down, afterwards to heal, and in this way tend to prevent a later extension of the disease. It is gratifying to note that these results were attained, not only in this case, but also in others of a similar nature.

PROFESSOR OSLER has been elected Dean of the Johns Hopkins University in succession to Dr. W. H. Welch, resigned.

ADIPOSA DOLOROSA: A MYXŒDEMATOID DYSTROPHY.

BY A CORRESPONDENT.

THE investigation of the disease now universally known under the name of myxædema, though considerably advanced by the attention of which it has been the object during the last few years, still presents many points calling for elucidation. Apart from the group of morbid phenomena which constitute a typical case of myxedema, it has been shown that there are many other conditions of which a myxœdematous tendency is a more or less prominent factor. There are many varieties of myxædema which have not yet been thoroughly investigated. although they present considerable interest in that they throw light on the pathological physiology of the thyroid gland as well as from a clinical point of view.

Among the abortive forms of myxedema, there is one which has already been sufficiently described by Dr. Dercum, of Philadelphia, to enable us at once to outline its general features, and to which this observer has given the name of adiposa dolorosa. This name has the advantage of directing attention to the two principal symptoms of the affection, viz., the appearance in different parts of the body of subcutaneous masses of fat associated with painful manifestations localised at these points. As far back as September, 1888, at the meeting of the Association of American Neurologists, Dr. Dercum brought forward his first example of this affection. The patient was a woman, at 51, who presented what was then described as "dystrophy of the subcutaneous tissues of the upper extremities and of the back with symptoms suggesting myxœdema." Two years later Dr. F. B. Henry communicated to the Neurological Society of Philadelphia a very similar observation, and during the following year Dr. Dercum, having met with a third case of the same kind, undertook the investigation of the pathology f the so-called painful adiposis, emphasising on one hand the myxedematous character of the syndrome, and, on the other, the points of distinction which differentiate it from the classical idiopathic myxædema. More recently still two further contributions devoted to this subject have made their appearance, one by Dr. Spiller and the other by Dr. Eshner. The former describes three fresh examples of painful adiposis, two of which he had had an opportunity of studying in Dr. Dercum's wards, together with one which had been communicated to him by Dr. Hay. Dr. Eshner relates a case of the kind, also from the clinic of Dr. Dercum, adding a previously unpublished observation by the latter. In looking through the medical literature of the last few years one meets here and there with a number of observations on myxedema which present a certain, and in some cases a striking, analogy with the condition under consideration. Nevertheless, as it is only in America that these cases appear to have been observed and described in a thorough and complete manner, it is to American authors that we must look in order to obtain a comprehensive idea of the pathological state now known as "painful adiposis.'

Judging from these observations the malady in question appears to affect exclusively persons of the female sex. It is generally met with in middle-aged or elderly people though it has occasionally been observed comparatively early in life—in one case at the age of 29.

The pathogenesis of the affection is obscure. In some cases there has been a history of alcoholism, syphilis, or rheumatism, but in other cases these etiological features have been absent. In one instance traumatism appeared to have had a share in its production, the onset of the malady dating from a carriage accident, as the result of which the patient was pitched out on to the road, and remained for a time unconscious.

In its fully developed condition the disease is characterised to begin with, by the presence of disseminated subcutaneous masses of fat. The distribution of these masses is usually very irregular, though occasionally there is a semblance of symmetry These masses, which vary considerably in size, may attain considerable dimensions. They first appear in the form of small nodules which grow slowly, while other tumours of the same nature continue to make their appearance in other regions of the body. These local deposits of adipose tissue occur on the legs, thighs, arms back, and abdomen, and they never invade the face, hands, or feet, or the body as a whole, and never culminate in a general uniform obesity. always remaining separate and distinct, with a well-defined outline.

More or less soft to the touch at the beginning, these fatty deposits ultimately acquire a firm consistency. They are often lobulated to an extreme degree, and on palpation give the sensation of a bundle of worms or rolls of cord, resembling in this respect the sensation given on palpating a varicocele. Microscopical examination of portions of these tumours showed simple hyperplasia of the adipose and connective tissues.

Another salient feature of these localised collections of fat is that they are associated with pain. This sometimes occurs spontaneously, at others only on pressure or on movement. In certain cases the symptom pain has preceded the appearance of the fatty overgrowths, being felt at the spots where the latter make their appearance later on. There is no uniformity in this relationship for in some patients the painful manifestations did not supervene until the tumours had attained a certain size.

Lastly, paroxysms of acute pain have been noted as occurring coincidentally with a sudden and rapid increase in size of the fatty masses. The thyroid gland in these patients often presents a marked degree of atrophy. Several other symptoms are occasionally observed, though less constant and of secondary importance, such as pain on pressure over nerve runks at the root of the affected limbs, areas of hyperæsthesia and anæsthesia, muscular and general enfeeblement, diminution, and even suppression of sweat secretion, headache, a tendency to hamorrhage from the mucous surfaces, and bronchitis. The affection is essentially of a chronic nature. Its onset is insidious, and the disease runs a slow and uncertain course, culminating, it may be, sooner or later in marasmus and dementia. Except at the terminal stage, in which the influence of senility must be allowed for, there is not, as a rule, any mental disturbance. At the post-mortem examination of two women suffering from painful adiposis the thyroid gland was hard, and infiltrated with calcareous deposit.

It is obvious from the description which precedes that painful adiposis differs from ordinary obesity in that it is associated with a whole series of symptoms which are not met with in the latter. It, on the other hand, presents mani est points of resemblance with ordinary myxœdema from which it differs however in the fact that the face, hands, and feet are not invaded, by the absence of mental disturbance and slowness of speech, as well as by the pain which is never absent in adiposa doloro-a. The myxedematous nature of the condition is, however, hardly open to doubt if we consider its symptomatology and the beneficial action on this affection of the thyroid treatment. Under its influence the fatty growths retrogress, the pain subsides and all the other symptoms undergo parallel improvement. Methodical massage, it is worth noting, has been found a very useful adjuvant of the thyroid treatment.

WOMEN QUACKS

IN THE

SEVENTEENTH CENTURY.

By JABEZ HOGG, M.R.C.S.Eng.,

Consulting Surgeon to the Boyal Westminster Ophthalmic Hospital, and to the Hospital for Women and Children.

It is very well known that strange notions prevailed on the art of healing in the days of Charles II., even among the higher classes of society, but it is not so generally known that the women quacks of the period were very numerous, and most pertinaciously press-ing in their attentions upon the sick and in the administration of "their infallible cures" than the regularly recognised physicians of the period. Many curious instances of this are given in the "Verney Memoirs." As an instance, the wife of one of the son's is stated to have gone "hopelessly mad," when more than one woman quack presented herself and offered "a certain cure" for the malady. One Mrs. Clark, promises an infallible cure for the sum of £20. Her mode of cure is not given. A certain widow, Scott, residing at Lawn Farm, presses her services upon the family. Her nostrum, as all nostrums usually are, was a secret one. A marvellous powder that sends the patient to sleep for three or four days and nights, and he or she wakes up perfectly cured. Ultimately, old Judith is permitted to try her skill, after giving "her devout assurance that she will not use any manner of sorceries, charms, or magic." Her "perfect cure!" consisted in taking the head of "a Jack-hare, wrapping it up in a new piece of cloth, and binding it tightly round the head of the patient, there to remain for three or four days, taken off and put in the centre of a pillow made of feathers, which must be slept upon until the cure is completed." This not being attended with any imcompleted." This not being attended with any improvement, the husband was "bidden to have his wife prayed for during six successive Sundays," but "the melancholy distemper remained uncured

It was, however, during the return of the terrible years 1665-66, when a hecatomb of victims (over 70,000) were carried off by the Plague, that quacks, male and female, had a high time of it: when, indeed, the women quacks were no less to the fore than those hailing from the Royal College of Physicians. Then it came about that every atrocious nostrum of this besotted period was brought forward and prescribed. One Cary Gardiner boldly proclaimed that she had a cure "warranted to put an end to the plague, "if she could only get enough of it." Meanwhile, the official remedy for the poorer folk was garlic and butter, with a clove or two added." the richer patients, able to call in a physician (not one of whom seem to have been a whit wiser than their old women rivals), costly powders were prescribed, consisting of "hartshorn, pearls, corals, tormentil, hyacynth-stone, onyx, and east hunicornhorn." Aunt Johan exhorts Sir Ralph "to wear a quill filled with quicksilver, sealed over with wax, and sewed up in silk with a string to wear about his neck." This she offers "as sarting to wear about his neck." In s she offers "as sartine as anything to keep one from taking the plage." Moreover, "if you let your horse wear it it will never have the disease." Sir Nathaniel Hobart, who while residing in town, "hopes God will preserve him, particularly as my doctor has purged and blooded me." "Lent figs were largely prescribed. The Eton boys were ordered to smoke in school daily and disinfectant, which they doubtless much enjayed. us a disinfectant, which they doubtless much enjoyed. No physician was wise enough to devise the cause, much less treat the dire disease. No one was able to

convince the City authorities that plague is a dirf disease, for the most part due to overcrowding in neglected insanitary dwellings. This will be seen; to hold true with regard to the Indian outbreak, so the never-to-be-forgotten plague of 1665 was fortunately followed the next year by the Great Fire of London. which at length swept it away; thus proving a real blessing in disguise, a perfect God send at the time, and a useful lesson to succeeding generations."

Clinical Records.

TWO CASES OF LATERAL SINUS PYÆMIA. (a)
By James Kebe, M.A., M.D.,

Surgeon to the Bradford Eye and Ear Hospital.

The first patient was a boy, æt. 15, who had suffered from ear discharge for several years. On admission there was paresis of the right side of the face and loss of taste of the right side of the tongue. The right mastoid was opened and a cavity filled with stinking cholesteatomatous material was emptied. Two days later a superficial abscess formed over the temporal bone, and was opened. The temperature, however, still rose to 104 in the evening and fell to normal in the morning. The sigmoid sinus was then explored, and thick green pus found about it. This was cleared away, the opening packed with gauze and the jugular vein ligatured.

No improvement occurred—facial paralysis was now marked. A week after admission pneumonic symptoms began, together with constant diarrhea, and the child

died a fortnight after admission.

Anti-streptococcic serum was administered but pro-

duced no good effect.

At the autopsy there was found extension of the thrombus back in the lateral sinus and up the petrosal sinuses.

There was discoloration of the bone, and erosion and

pus about the jugular foramen.

Several perforations of the walls of the jugular vein were found and the infection appeared to have reached the sinuses by extension from the floor of the middle ear through the vault of the jugular dome.

CASE 2.—A boy of five years who had suffered from ear discharge for a considerable time; shortly before admission an abscess had been opened behind the ear.

When seen on November 12th the temperature was 97.2, pulse 104. Next morning the pulse was 140 and temperature 103.6; he was mentally clear; no headache or pain; the tongue was dry and furred, and discharge was free. There was no thickening about the jugular vein, and no rigors or retraction of neck.

Operation, November 13th.—An incision was made over the left mastoid bone, and a considerable area of bone was found to be bare. Pus was found deep in mastoid on chiselling, but no discharging track was noticed. The lateral sinus was then exposed freely backwards, and seemed to be greenish-blue in colour and thrombosed. The jugular vein was ligatured in two places and divided, and the septic clot scraped away. There was free bleed ing, which was controlled by plugging. The whole wound was rubbed thoroughly with iodoform and boracic acid. The patient was collapsed, as the operation had lasted 100 minutes. The after progress of the case was at first unsatisfactory, and injections of antistreptococcic serum were given, but the fever still continued, and there was pain in the chest. On May 20th, a week after the previous operation, the wound was reopened and the sinus traced back till healthy vessel was reached, it was thoroughly scraped out and plugged with gauze.

The middle ear was curefted, and together with the mastoid antrum made aseptic as far as possible. Serum injections were given again at intervals of thirty hours. The cough continued for a few days, but apart from this the case progressed satisfactorily, and the boy was able to return home on December 20th.

(a) Read before the Bradford Medico-Chirurgical Society, Jan. 17th, 1899.

It is worthy of note that recovery in these cases is unusual after chest symptoms have appeared. The use of the serum appeared to have produced no beneficial defact, and seemed on the other hand to temporarily derange the appetite for food. Early operation was advocated in cases of otitis media where there is a fluctuating temperature.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON. MEETING HELD WEDNESDAY, FEBRUARY 1st, 1899.

Dr Cullingworth, President, in the Chair.

THE ANNUAL ADDRESS.

THE PRESIDENT, after some introductory remarks, commented on the fact that there was a further slight falling off in their numbers. In January of last year the number of Fellows was 711, comprising eleven honorary and corresponding Fellows, and 700 ordinary Fellows. During the past year the Society had lost twelve F-llows by death, and thirty by resignation. The number of new Fellows elected was twenty-two, so that there was a deficit of nineteen, and he urged them to be-tir themdenct of intereen, and he urged them to be tir themselves to keep up the supply of new Fellows. Referring to the issue by the Council during the past year of a well considered code of "Rules and Regulations to be Observed by Midwives holding the Certificate," he observed that it had long been felt to be an anomaly that there were no such rules, especially as a phrase in the declaration which every midwife who had passed the examination was called upon to sign before receiving the certificate, seemed to take their existence for granted. He regarded their preparation and publication as the most important event that had occurred in the history of the Society during his term of office as President. He of the Society during his term of office as President. He did not suppose that these "rules and regulations" would meet with universal approval, but he thought it would generally be conceded that they go a very long way towards meeting the requirements of the case. The work of drawing up these rules was undertaken by the Council and the Board for the Examination of Midwives jointly. In the matter of the examination for midwives, he admitted that the Society still continued to suffer from a certain amount of professional opprobrium, which, though entirely under fessional opprobrium, which, though entirely undeserved, was probably in some degree responsible for the decrease in their numbers. He declined to argue the point on that occasion, but he would remind them that the Society had undertaken the work from a sense of duty and merely as a temporary expedient, after having tried in vain to induce the Government to move in the matter. He added that they would be only too glad to relinquish the task whenever the State could be prevailed upon to take upon itself functions which properly belonged to it, and which it alone could adequately fulfil.

Passing on to the scientific work of the past session he congratulated the Fellows upon an excellent record, papers having been unusually numerous Ten of them dealt with obstetrical, and five with gynecological subjects. He passed the various papers briefly in review, and then proceeded to the lugubrious task of giving a short biography of the deceased Fellows. In conclusion, he took leave of the Fellowson the termination of his term of office as president thanking them all, and especially the secretaries, for the assistance they had rendered to him in his task. In resigning the chair, he had, at any rate, the satisfaction of knowing that the next occupant would be one, whose contributions to scientific gynæcology, they must all be proud.

After the usual vote of thanks had been agreed to Dr. GRIFFITH suggested that the new rules bearing on midwives should be freely circulated among the Fellows, most of whom were in a state of profound ignorance of their purport. Although himself in cordial accord with the Council in the work in which they were engaged he could not disguise from himself that the action of the Society in regard to the examination of midwives was extremely unpopular with the profession at large. He defended his predecessor in the Presidency of the Medical Defence Union (Mr. Victor Horsley) from certain aspersions cast upon him in respect of his action in regard to the examination of midwives and urged that greater publicity should be given to the subject.

The President pointed out that the new rules were bound up with the volume of Transactions shortly to be issued so that they would be accessible to the Fellows at large. He deprecated any proposal to take the sense of the society viewed as individuals on the question as not conducive to peace. The new rules had already been forwarded to all midwives on their register.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD FEBRUARY 1ST, 1899.

SIR JOHN BATTY TUKE, President, in the Chair.

ADDISON'S DISEASE.

Dr. R. A. Fleming showed a mother and four children apparently suffering from Addison's disease. In the case of the first-named the pigmentation had begun seven years ago, and had grown deeper with each successive pregnancy. Recently numerous small pigmented moles had appeared. There was no discolouration of the mucous membranes. In addition the constitutional symptoms—ceaseless vomiting and diarrhea, palpitation and faintness, and excessive languor—were well marked. The eldest child, et. 7, had shown signs of pigmentation four years ago, and in her case, too, moles had developed. The remaining children, aged four, three, and two years, had become pigmented and the subjects of moles three years ago, six months ago, and seven weeks ago respectively. The three eldest also suffered from vomiting, diarrhea, and languor. There was no tuberculous family history, and the pigmentation and constitutional symptoms had somewhat diminished under the administration of arsenic. If these were really examples of Addison's disease the cases were probably

Mr. COTTERILL and Dr. Russell showed a patient after mastoid disease and empyema. The former had been secondary to the latter co.dition—an unusual sequence of events. Speaking of the operation, Mr. Cotterill deprecated the puncture of an exposed lateral sinus in order to solve an existing doubt as to the presence of thrombosis. It was quite easy to discover the state of the vessel by gentle palpation, and puncture from a septic wound was very liable to introduce germs into the general circulation

Dr. Shennan showed (1) vessels from a case of tuber-culous meningitis, demonstrating the enlargement of the endothelial cells lining the peri-vascular lymph spaces; (2) early tubercle of the urethra from a case of general tuberculosis; (3) organism in cancrum oris. In addition to the special germ, pneumococci, staphylococci, and streptococci were present, but the chief organism found was one resembling the Löffler bacillus. It was almost identical with the clubbed form described by Kanthack as an involution stage of the diphtheria organism. I'r. Shennan had found a quite similar organism in a case of acute spreading gangrene, and in one of phagædenatous chancre. In the former case culture through two generations had resulted in a growth identical with that of diphtheria.

Dr. R. A. FLEMING showed (1) two stomachs showing mammillation, and (2) a heart with aneurysm of one of the sinuses of Valsalva.

Drs. W. Stewart and John Thomson showed a specimen of congenital malformation of the esophagus. Immediately after birth it was noticed that the infant was unable to swallow, and on passing a gum elastic catheter it was found to be checked five inches from the mouth. On the third day of life a Witzel's gastrostomy was performed and the child fed. It progressed well for nearly a day, and then died suddenly. On post-mortem the cesophagus was found to be completely occluded, and there was a communication between its lower part and

the trachea; after being fed the child had vomited the food into its trachea and had been suff-cated. A similar complication had existed in other recorded cases.

Dr. P. McBride read a paper on

THE TREATMENT OF OZENA, WITH SPECIAL REFERENCE TO CUPRIC ELECTROLYSIS.

After alluding to the local atrophic condition in ozena, the speaker said that the methods of treatment in vogue might be considered under the following heads:—(1) Destruction of the secreting area by curetting, &c. This was now recognised as useless. (2) Stimulating and irritating applications, such as iodine, and nitrate of silver sprays. Plugs probably acted in a similar way, and mechanical stimulation by the use of vibrating pledgets of cotton wool had also been tried. (3) As an organism resembling that of diphtheria had been found in some cases of ozena, the injection of antitoxin had been employed, but though some benefit had undoubtedly resulted, the effect had only been temporary. (4) More recently cupric electrolysis had been recommended. He had tried this in a great number of cases, and recounted ten of these. In almost all great benefit, and in some a complete cure, had accrued. The advantage of this over all other methods of treatment was that subsequent douching was not required, and that even in the morning the smell was completely absent. The operation was very simple, cocaine being used as an anæsthetic. The copper (positive) electrode was thrust into the septum, and the steel (negative) electrode, into the inferior turbinate. A current of from 3 to 10 milliamperes was required, and each sitting lasted ten minutes. Three or more sittings might be needed. Local discomfort rarely followed the electrolysis. It was of interest to note that though only one nostril was treated, both participated equally in the benefit. The rationale of the method was unknown.

Drs. Logan Turner, Shennan, and Hunter spoke. Mr. Wallace read a paper on

MOVABLE KIDNEY.

After reviewing the literature of the condition, Mr. Wallace went on to discuss its pathology. He could not agree with the ordinarily accepted view that movable kidney was brought about by undue laxness of the abdominal parietes the result of repeated pregnancy; almost all his cases had been in nulliparse. Attention had recently been called to the fact that floating kidney was more common in childhood than was generally supposed; this, too, went against the above theory, and in favour of some congenital defect. In examining for a movable kidney, it was necessary to palpate all over the abdomen. He had seen the condition missed because the organ was lying low in the right iliac fossa. now performed the operation of nephropexy on fourteen occasions, and in all the patients save one, the symptoms had been completely removed In slighter cases a pad should be worn, and he showed a small inflatable rubber cushion which was intended to be sewn to the inner surface of the corset This was perfectly effective, cheap, and could often be worn when the ordinary belt was insupportable. The point to be attended to in the use of these pads, was that the kidney must be in the proper

position before they were applied.

Mr. COTTEBILL said that those cases which showed symptoms of renal calculus, and which were cured by operation, though no stone was found, were in all probability cases of movable kidney, and the operation was

beneficial by fixing the organ.

Dr. Russell stated that in a series of post-mortems on old women, it had been almost the rule to find the right kidney very freely movable under the peritoneum. He had never been able to find a satisfactory explanation of the condition.

Mr. Stiles and Dr. Church also spoke.

A SPECIAL general meeting of the Irish Medical Schools' and Graduates' Association will be held at 5:30 p.m., on February 22nd. at 11 Chandos Street, Cavendish Square, the President (Dr. Mapother) in the chair, to consider certain proposed alterations of rules.

LIVERPOOL MEDICAL SOCIETY.
MEETING HELD JANUARY 26TH, 1899.

R. S. ARCHER, M.D., Vice-President, in the Chair. THE VACCINATION ACT, 1898.

Dr. Permewan proposed the following resolution:—
"That the members of the Liverpool Medical Institution are of opinion that the Vaccination Act, 1898, wasenacted in direct opposition to the findings of the Royal
Commission; that the operation of the Act will beprejudicial to the public safety, and that its amendment
is urgently required."

Dr. Hors, in seconding the resolution, said he thought that the terms of the resolution were in no sense too-strong, and quoted extracts from the Report of the Royal Commission, showing that the Act is in direct opposition to the views which the Commission expressed. He also alluded to the mischief already resulting from the closing of the vaccination stations, which he considered most unfortunate and ill-judged.

The resolution was carried nemine contradicente.

Mr. C. Thurstan Holland showed radiographs of the normal chest of a boy, and also of the chest of a boy in whom the left aper was in a state of tuberculous consolidation. The difference was most marked, as also was the difference between the two sides of the affected child. This difference could also be plainly seen with the fluorescent screen. The exposure with a 10 in. coil was 60 seconds. This boy was æt. 6½.

THE REMOVAL OF TUMOURS BEHIND THE TONSIL.

Mr. MITCHELL BANKS described three cases of removal of tumours lying external to and behind the tonsil, with lantern slide illustrations. The first case was that of a young man in whom the tumour had been growing for many years, and had attained such a size as to cause a marked projection behind the vertical ramus of the jaw. It was removed by the mouth. A vertical incision. being made over it, it easily shelled out without hæmor-rhage, and was found to be an adeno-fibroma as had been diagnosed. The second was a precisely similar case in a woman of forty, with a history of ten years' growth. of the tumour. As she was very stout and full-blooded. a preliminary laryngotomy was done, and the pharynx packed with sponge, but the bleeding was only trifling, and the tumour was easily shelled out with the finger. The third case was different, the patient being a small, thin, pale woman, about twenty years of age. A swelling had appeared behind the right tonsil about eight or ten weeks before her admission, and had been steadily and rather rap dly increasing. There was a great deal of pain in it, and the swallowing was seriously interfered with. The swelling was very elastic and ill-defined, insomuch that there was a question as to whether it might not be inflammatory, having as a focus some small, very deep collection of pus. Under chloroform an excision of an exploratory nature was made through the thinned and flattened out tonsil, the finger came upon a distinct tumour, which felt as if it could be shelled out, although clearly very adherent at the upper and back part. In about a fortnight the patient's suffering became extreme, and she was in danger of choking, so a preliminary laryngotomy was done and the pharynx plugged. Then a free incision was made over the tumour and enucleation effected. This gave a remarkable view of the deep parts, and when the growth was finally torn away it was found to be adherent to the side of the body of the third cervical vertebra, and to the base of the skull. Owing to very little use of cutting instruments the bleeding was slight. The jaw was drilled and wired, and the cheek and jaw soon united, but there is undoubted evidence that the tumour is beginning to grow from its deepest parts. Naked eye inspection and the microscope showed it to be sarcomatous.

Mr. PAUL referred to six cases of adenomatous tumourwhich he had met with on the palate and fauces. Threeulcerating and three encapsuled. The latter were perfectly innocent, but the former class sometimes showed amalignant tendency.

REMOVAL OF TUMOURS OF THE ŒSOPHAGUS BY PHARYNGOTOMY.

Dr. Permewan described two cases of tumours of Digitized by

the œsophagus which he had removed by sub-hyoid pharyngotomy. The first case, in which the growth was benign, died from the immediate effects of the operation; the second recovered without a rise of temperature. After describing the method adopted in each case, Dr. Permewan stated the conclusions he had arrived at in this operation, these were: (1) that sub-hyoid pharyngotomy is justifiable in spite of the large percentage of fatalities after it. (2) That it is admirably adapted for removal of growths from the lower pharynx, upper part of the esophagus, and also from the upper aperture of the larynx. As a preliminary to resection it is valuable as giving a more complete view than that obtained by thyrotomy. (3) That to insure a safe operation a preshould be made to close the wound after operation, but that it should be plugged by gauze and allowed to heal by granulation. (5) That feeding should be by the cesophageal tube exclusively.

Mr. Robert Jones read a paper on

SOME POINTS IN THE SURGERY OF THE PARALYSIS OF

He deplored the lack of interest displayed by the profession in the treatment of these affections. This was due to the pessimism derived from the pathology. It was essential that there should be surgical supervision almost from the onset, as without mechanical and operative help the physician was powerless. The pathology required working up and further experiments made. should consist of inoculations at an early stage, and of a search for the microbe. In view of receut experi-ences of his own, of outbreaks of an epidemic character at Stockholm, in America, and in Australia, there was strong evidence of the influence of infection. With care, most of the deformities of polio-myelitis, might be avoided, more especially those due to contractures, and by mechanism so applied as to equalise groups of antagonistic muscles, apparently very old paralyses, could be remedied. A diagnosis, often difficult, should be made between a paralysed group of muscles and a group merely rendered us-less by the un-controlled action of opponents. Mr. Jones discussed the question of tendon-grafting and the conditions suitable to it. He thought the operation likely to prove very valuable in a number of cases. He had operated upon five cases. In two he had inserted the sartorious into the tendon of the paralysed quadriceps. In two cases he had inserted the peronei into the paralysed tendoachilles, for talipes-calcineous. In one case he reinforced the tibialis-anticus by means of the peroneus-longus. In a case of talipes equino-valgus, the peroneus longus may be inserted into the tibialis posticus, or instead of the peroneus longus, a strip of the tendo-Achillis. Mr. Jones had operated upon over 66 flail joints in accordance with the rules he laid down in 1894, suppuration only occurred in one case. No matter what the trophic changes, healing seemed to occur without hindrance. He often anchylosed both knee and ankle at the same operation. In talipes-calcaneus a good view of the joint might be got from behind, the cartilage freshened, and the tendo-Achillis could be at the same time shortened. This operation he substituted for Nillet's. After obtaining either short fibrous or bony anchylosis in knee or ankle, the psoas and iliacus muscles moved the limb in one piece, and so expensive and troublesome appliances could be dispensed with. In dealing with spastic paraplegia, Mr. Jones combated the dicta of neurologists in regard to tenotomies. He divided the tendo-Achillis, and any other tendons which were tense, and in obstinate cases, exsected portions of the adductors. Both limbs were then kept in extreme abduction for several weeks; very fair walking results were obtained. In very spasmodic cases he strongly urged arthrodesis.

Mr. PAUL quoted, in support of Mr. Jones's advocacy of tendon grafting, the result obtained in a case of which the distal end of the long flexor of the thumb was grafted on to that of the index finger. The boy ultimately became a fair pianist, and could flex either digit independently, presumably by automatic action of oppos-ing muscles. The paper was further discussed by Drs. Murray, Warrington, Paul, and Barr. BRADFORD MEDICO-CHIRURGICAL SOCIETY. MEETING HELD ON JANUARY 17TH, 1899.

The Vice-President, MR. HORROCKS, in the Chair.

Dr. Enrich gave a microscopical demonstration. Dr. RABAGLIATI showed a tumour of the uterus weigh-

ing 11 lbs., which had been successfully removed. The tumour was found to be a fibro-myoma. The case was complicated by the presence of a malignant tumour in the left breast.

CASES SHOWN.

Subconjunctival dislocation lens-Dr. A. Bronner. Luxation of lens into anterior chamber—Dr. Kerr. Child recovered from lateral sinus pyamia-Dr. Kerr. Lupus of face and neck-Mr. Althorp.

Dr. Kerr read notes on "two cases of lateral sinus pysemia,' which will be found under the head of "Clinical Records."

Mr. ALTHORP read notes on

A CASE OF LYMPHO-SARCOMA,

involving the stomach, colon and rectum. The patient was an unmarried woman, set. 29, a cook. The first symptoms of illness were in June, 1898, and consisted of diarrhœa and vomiting, with fever The fever persisted, but the other symptoms subsided with rest in bed. On Sept. 10th she was admitted to hospital with symptoms of chronic intestinal obstruction, and on examination a growth of the rectum was found. It infiltrated the surrounding tissues, and almost blocked the lumen of the gut, not allowing the passage of the finger past the obstruction. Left inguinal colotomy was performed on September 21st, the fingers introduced into the abdominal cavity felt the pelvic contents matted together. The patient progressed satisfactorily, and the bowel was opened on the fifth day. For about six weeks the patient did well and was able to be up and about the ward, but at the end of that time began to complain of abdominal pain until her death on November 16th. There had been free discharge of fæces all this A fortnight before death a swelling was noticed in the position of the transverse colon, and during the last week of life she vomited freely. At the autopsy there was found a growth involving (1) the stomach in its pyloric half, the small curvature, and spreading up to the cosophagus; (2) the cæcum, ascending and transverse colon; (3) the rectum matting together the pelvic contents. There was only one secondary growth, which was in the bronchial glands. Mr. Althorp remarked on the extensive nature of the growth, which had caused no obstruction, except in the rectum The treatment of rectal growths was also discussed.

Dr. Enrich gave a description of the microscopic appearances of the growth, pronouncing it to be a lymphosarcoma. He discussed the nature of lymphosarcomata, and suggested a parasitic origin in the case under consideration, although there was no direct evidence in the shape of organisms. He remarked that there was a pigment in some of the cells of a faint, greenish colour. He did not consider the deposit in the bronchial glands a secondary growth, but a primary manifestation.

Drs. Horrocks, Goyder, Hall, and Metcalfe, discussed the case.

NORTH OF ENGLAND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT MANCHESTER, JANUARY 20TH, 1899.

The President, Dr. Donald, in the Chair.

SPECIMENS.

1. Dr. Briggs (Liverpool) showed a Soft Fibroid umour removed from the Uterus by Enucleation Tumour through the Abdomen.

2. Dr. NATHAN RAW showed a Ruptured Uterus, with an Ovarian Cyst, removed by Abdominal Section, after delivery of a child at full term. The patient, a multipara, had been in labour for three days, under the care of a midwife. She was then seized with intense

pain in the abdomen and hæmorrhage, with great collapse. On admission to the hospital she was pulseless, and four pints of saline fluid were transfused into the median basilic vein with very beneficial results. On examination, the vaginal vault was pushed down by a large firm swelling behind the uterus, suggesting an ovarian tumour. The cervix was high up under the pubes. The umbilical cord was prolapsed, and the placenta lay in the lower uterine segment. This he rapidly detached and a foot was brought down. A loop of intestine was then found lying in the uterine cavity showing that the uterus was ruptured. The child was quickly extracted, and a large tear in the posterior wall was then discovered. Saline fluid was again transfused, and abdominal section at once performed. The peritoneal cavity contained a large quantity of blood and clots, and the contents of the ovarian cyst which had undergone tension had ruptured. The uterus was rapidly amputated, and removed together with the cyst. The petient rallied well, but gradually sank, and died from exhaustion on the third day.

Remarks were made by Drs. Lloyd Roberts, Sinclair,

Wright, Walter, and the President.

Dr. T. ARTHUR HELME read the notes of a

CASE OF DEGENERATING FIBROID REMOVED ALONG WITH THE UTERUS BY ABDOMINAL HYSTERECTOMY.

The patient, æt. 29, had suffered for ten months from hæmorrhage and severe pain, and on one occasion had retention of urine. The pain came on after the use of ergot. Previously she had not felt any pelvic pain. As the hemorrhage was only controlled by plugging the uterus, it was thought advisable to operate. The uterus was therefore completely removed through the abdomen. The vaginal roof was covered with a layer of peritoneum detached from the anterior surface of the uterus and carefully sutured. No drainage of any kind was employed. The patient made an uneventful recovery. The tumour was found to occupy the posterior wall of the uterus, and had become partially extruded into the cavity occupying also the upper part of the cervical canal. A point of interest was the effect of the administration of ergot in setting up violent uterine contractions, resulting in severe pain, and also causing partial extrusion of the tumour and leading to increase of the hamorrhage. The degeneration appeared to be the result of partial cutting off of the blood supply to the tumour.

Remarks were made by Drs. Walter, Davies, Lloyd

Roberts, Briggs, and the President.

Dr. W. E. FOTHERGILL read a paper on some

AUTO-INTOXICATIONS OF PREGNANCY.

The presence of albumen in the urine of eclamptic women, and the occurrence of various lesions in the kidneys, the author remarked, had led to the view that eclampsia was of renal origin. This theory, however, has of late years been questioned by many. Albumen may be absent from the urine. Again, the urine, though small in quantity, is low in toxicity, whilst the blood serum is much more poisonous than in health. The constant presence of necrotic and hæmorrhagic lesions in the liver has led to the view that in these cases this organ is really at fault. Jaundice is sometimes associated with eclampsia, and in acute yellow atrophy of the liver, which is peculiarly liable to occur during gestation, the lesions in the liver are an exliver, aggeration of the changes met with in eclampsia. It is probable then that eclampsia should be regarded as an auto-intoxication of hepatic origin. The various affections of the nervous system during pregnancy, such as polyneuritis, myelitis, &c., are clearly toxic in orgin. Melancholia and mania of pregnancy have probably a similar origin. A number of the slighter ailments of gestation such as vomiting, salivation, pruritus, neuralgia, and the changes of temperament, are regarded by many writers as manifestations of minor degrees of auto-intoxication. When the extra strain thrown upon the various organs during pregnancy is considered, it is easy to understand that a disturbance of the equilibrium between poison production and poison destruction may readily occur, and it is found by observation that the blood serum is more toxic during gestation than in health. The subject is by no means fully worked out, but the

auto-intoxication theory forms a useful working hypothesis, and may help, by associating a number of diverse conditions together, to afford a new grouping of these troubles. It is probable in the future that a number of these morbid conditions will be united under the term hepatic toxemia, as suggested recently by Pinard.

Dr. GEMMELL said that in the puerperium many cases with pyrexia, which were classed as septicemia, were really examples of toxamia, arising from the liver, kidneys, or alimentary tract. He related a case in which the patient after natural labour had pyrexia and quick pulse, with an absence of any local signs. The blood and lochia were examined bacteriologically, but no streptococci were found. At the end of four days suppression of urine came on, and the patient died of uræmia. At the autopsy no evidence of disease of the kidneys could he discovered.

Dr. WRIGHT and Dr. WALTER also discussed the

paper.
The following were elected Office Bearers for the year
Vice Presidents. Drs. J. 1899:—President, Dr. Donald; Vice-Presidents, Drs. J. Benson, J. Braithwaite, J. Cregeen, W. E. Fothergill, J. E. Gemmell, C. Richardson, J. Sinclair, and G. Thorpe; Hon. Treasurer, Dr. Richard Farrell; Hon. Gen. Secretary, Dr. Arnold W. W. Lea; Council, Drs. R. A. Brantary, Dr. Arnold W. W. Lea; Council, Drs. R. A. Brannigan, E. Buxton, C. Gwynne, D. L. Hamilton, T. A. Helme, J. B. Hellier, T. D. Leigh, J. Matthews, E. H. Monks, S. Nesfield, W. Smith, Lloyd Roberts, J. E. Scowcroft, J. P. Stallard, J. D. Martin, D. Smart, C. Breker, W. Walter, A. E. Wear, and R. E. Williamson; Honorary Local Secretaries, Dr. John Scott (Manchester), Dr. W. Fingland (Liverpool), Dr. E. O. Croft (Leads) H. Rhodes (Sheffield). (Leeds), H. Rhodes (Sheffield).

Mrance.

FROM OUR OWN CORRESPONDENT.

Paris, February 5th, 1899.

HERNIA AND THE BICYCLE.

M. Lucas-Championniere read a paper on the cure of an inguinal hernia by the use of the bicycle, and declared that for a long time he had considered that rest generally advised to persons with rupture was much less beneficial than muscular exercise. It was easy, he said, to observe that working men tolerated much better their hernise than habitually inactive persons. All kind of sports could be recommended to ruptured individuals, but that of the bicycle was the best of all. In a person seated on the machine the hernia had no tendency to come out, it remained in the abdominal cavity and disappeared in time. The bicycle exercise improves besides the general health, and produced a decrease in the embonpoint, which was greatly to be desired in such cases. To obtain this result, the bicycle should be used according to method; the person should be seated on a low saddle, and as much behind the axis of the pedals as possible; uphill or rapid riding should be forbidden.

M. Robin related seven cases of acute articular rheumatism, and one case of acute blenorrhagic rheumatism treated by methylene blue. In all the cases, save one, this drug proved equal to salicylate of soda. Never was any unfavourable symptom observed through its employment on the condition however, that the methylene used was chemically pure.

TUBERCULOUS ABSCESSES.

M. Lannelongue spoke, at the Academy of Sciences, on the treatment of tuberculous abscess, and said that it was rare that such abscesses got well spontaneously, and generally they required early intervention, consisting in extirpation of the tumour or in successive modificating injections.

The ablation by the bistoury of all the purulent collection was naturally the ideal method, if the tumour could be removed without opening it; but each time that the cyst was more or less voluminous or deep-seated there was risk in opening it in dissection. Consequently it was preferable to empty the cyst first, and then use the curette on the walls. But this method was attended with some danger, as it exposed to general infection, by the introduction of the bacilli into the open vessels, and one was never sure that a portion of the virulent disease had not been left behind. Injections, on the other hand, gave excellent results when properly practised,

The trocar should be of a certain size, and passed through a portion of the healthy skin. Once the pus was evacuated, the cyst should be washed out with a one per cent. solution of phenic acid until the returned liquid was seen to be perfectly pure. Then an ounce of the following solution should be injected:-

> Iodoform, Creosote, 3ss.; Sweet almond oil, 3iij.

Out of 17 patients thus treated, 4 got well after one injection, 3 after two, 3 others after four, and 1 after five injections, while the remaining 6 had fistula and got well in from ten months to two years.

POST-PARTUM HÆMORRHAGE.

Prof. Bastian, of Geneva, recommends in the treatment of post-partum hæmorrhage the following simple operation:-A bivalve speculum is introduced and opened as largely as possible, and after cleaning out the clots, iodoform-gauze is packed in until the whole cavity is filled. But the point in the method is that the speculum is left in situ. At the end of twelve hours it is withdrawn with a portion of the plugging, and twenty-four hours later the remainder is removed.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 4th, 1899. CURATIVE INSTITUTIONS FOR PHTHISIS.

At the meeting of the Society for Innere Medizin of the 9th inst., Hr. von Leyden reported on the action of the Central Committee formed for the furtherance of the scheme for the erection of Institutions for the treatment of phthisis. The committee had decided to summon a Congress in Berlin in May for the consideration of steps for the campaign against tuberculosis. For the various divisions of the subject, ætiology, prophylaxis, and treatment, distinguished physicians would be selected to introduce the subjects. As regarded the Berlin-Brandenburg Branch Society there was a steady development that had overcome various difficulties, such as ways and means and the site of the proposed buildings, and the results, so far, had been satisfactory. Their means would suffice for the erection of an Institution in Belzig. To this would be associated Bleichröder's endowment. The Institution would afford accommodation for 100 beds, and for the success of the undertaking the speaker called upon all medical men to try to obtain the active interest of their clients.

Hr. Milchner then followed with a note on THE CELLS IN THE ASCITIC FLUID OF LEUCEMIA. Ehrlich and Lazarus had proposed the question

whether it was possible to distinguish between the active and the passive forms in leucocytosis, i.e., whether leucocytes found their way into the blood by their own movements (active form), or whether they were swept there mechanically (passive form). In the first group the cells must move towards an inflamed part, and be met with in the exudation. This was so in the polynuclear form in eosinophilia (such as pemphigus and bronchial asthma), in which the eosinophile cells are found in the inflammatory products. In the second form no wandering of the leucocytes took place, and accordingly they were absent in the inflammatory products. Whilst in lymphocytosis there was proof that the form was active, in myelogenous leucæmia there was no certain proof of it, although Ehrlich believed it, and in a pleuritic effusion had seen " Mast " cells. The speaker had now made dry preparations, from the ascitic fluid from a case of leucæmia (myelogenous form), stained with eosin, methylene blue, which showed all three forms of cells, so that the myelogenous form might also be considered active.

Hr. L. Jacobson then read a paper on

CHANGES IN THE SPINAL COLUMN AFTER PERIPHERAL PARALYSIS.

He showed preparation from a case of recurrent cancer of the left breast that had implicated the nerves in the clavicular fossa. Pain came on in the left arm; it began to swell; motor weakness showed itself that soon developed into complete paralysis. There was also great disturbance of sensibility, first on the inner, then on the outer side of the arm. Muscular atrophy of the deltoid and of the supra and infra spinatus, faradic and galvanic excitability completely extinguished. The diagnosis could not be doubtful; paralysis of the left brachia, plexus from pressure. The diagnosis was confirmed after death. The brachial plexus, along with the vessels, was removed. The nerves were grey-coloured; they had undergone gelatinous degeneration; the axillary vein was completely blocked by thrombosis, hence the ædema. transverse section was made through the plexus and stained. No nerves contained medullary tissue, as only a comparatively short time elapsed between the commencement of the symptoms and death, the case was suit able for determining what change had been set up in the spinal cord. The cord was therefore removed without any trace of cancerous disease being discoverable in it. The changes found must, therefore, have been purely secondary. The cord was treated in various ways for the purpose of microscopic examination. The cells of the lateral column of the anterior horn were rounded off, without processes, pale, the nucleus was absent or eccentric, the median cells unchanged. In the lateral horn also the cells were smaller and thickly pressed together—on the left, full numbered but highly coloured; on the right, deficient in number and atrophied. The anterior roots on the left were slightly atrophied. Sensory parts: the posterior roots distinctly degenerated. Atrophy of the cells in the lateral columns and in the posterior horn; some descending roots were also changed. The condition found was of pathological interest. Von Leyden first gave expression to the opinion that degeneration of the posterior column in tabes dorsalis was secondary to lesion of the posterior roots. This view was now generally accepted. A controversy had now begun as to where the tabetic process commenced. Von Leyden assumed that it begun in the periphery, and the secondary

retrograde lesion was in favour of this. Against this it had been objected that the tabetic lesion was considerably greater than that of the simple secondary lesion. This case, which comprises both recent and older degenerations, which showed a degeneration gradually increasing with length of time was in favour of the correctness of von Leyden's views.

THE PREVENTION OF CHILDRED FEVER.

This much discussed subject has again recently had attention drawn to it by an article in the Berl. Med. Wochensch, 46/98, by Prof. Hofmeier, of Würzburg. In a recent work he sought to show that obstetric wards could be made full use of for teaching purposes with perfect safety, so long as proper measures for disinfection of hands and genital passages were adopted and rigidly enforced. As temperature may be looked upon as a reliable test, the "surest touchstone" in fact of normal childbed, the noting of the temperature should be above suspicion. He has therefore published a record of another (fourth) thousand cases of labour in which the temperature was taken throughout by a physician instead of in the usual way by a nurse. In the thousand cases there were seven deaths, but these were all due to grave obstetric complications or general diseases. There was no case of infective disease in the general sense in the whole series. The cases therefore demonstrate the correctness of the position he has taken up, that obstetric teaching is no bar to successful management of the puerperal state. He attributes the excellent results obtained, not to any superior sanitary arrangements, as the clinic stands far behind some modern institutions in this respect, not to any complicated methods of disinfection and sterilisation, such as are carried out in many places, but simply and alone to the method of treating lying-in cases always followed in the Würzburg Klinik, viz, that of thorough disinfection by means of 1 in 2,000 solution of subli mate.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 4th. 1899. THE NEW DRUG HEROIN.

TAUSYK has been experimenting with this new sedative for some time past, and has now ventured on a report of sixteen cases. Among these are eight suffering from phthisis pulmonalis, one of croupous pneumonia, one of pleuritis, and four of bronchitis. In all these cases treated with heroin the cough was immediately checked, or greatly modified, as the action of the drug is rapid and potent in its effects. The subjective symptoms are speedy relief and perfect comfort. In one case of bronchial asthma 0 003 of heroin relieved great dyspneal distress, which has not since returned.

In other experiments he tabulates the comparative values of heroin and morphia.

In cases of chronic cough which have lasted for weeks he has repeatedly given 0 003 gramme (0.046 of a grain) of morphia without the slightest amelioration, while the same quantity of heroin checked it instantly, and left the patient in a vastly improved state of health after its effects had passed off. In other cases 0.06 to 0.10 (0.9259 to 1.543 grains) of codeia was given with little or no effect, while 0.003 gramme (0.046 gr. of heroin gave

perfect relief. Similar success attended a case of phthisistreated with codeia, ext. of opium, hyoscyamus and morphia.

Heroin is also potent as an anodyne in cases of neuralgia in the trigomini, enteralgia, and hemicrania, while its efficacy in diabetes is undoubted.

After long use the dose requires to be increased to 0.005 gramme, owing to the peculiarity of babit. There is only one case where stupor or giddiness was observed from the long and repeated use of the drug.

Tausyk prefers giving it in powder form with sodse bicarb, &c., one hour and a half before food. Here commends that the quantity taken daily should not exceed 01 gramme or 15,432 of a grain, which might be increased in extreme cases to 0.03 grammes or 0.4,629 grains. Its greatest virtue, however, is in the relief of cough, which renders it invaluable in phthisical coughs.

TANNOPIN.

Tannopin, according to Fuchs, is a combination of tannin and urotropin, possessing the astringency of the former and the anti-bacterial action of the latter. It is, therefore, useful as a styptic and disinfectant in the alimentary canal. It contains 87 per cent of tannin and 13 per cent. of urotropin. It is of a yellow colour, hygroscopic, soluble in water, alcohol, and ether, but slowly dissolved by weak alkalies. In an alkaline canal the tannopin is split up into its component parts. This new drug has been used with benefit in cystitis, enteritis, &c., but requires to be given in good large doses of 4 grammes. In chronic conditions it is not so effectual, unless in cases of diarrhoa, when both forms are benefited by its use.

TABES DORSALIS AND NERVE STRETCHING.

At the "Gesellschaft der Aerzte," Benedikt showed a man on whom he had successfully operated by stretching the nervus ischiadicus, which quite relieved the pain, removed the paræsthesia, and restored the functional activity.

This operation is contra-indicated where the respiration is impaired or interfered with, in consequence of laryngeal irritation. In suitable cases, however, he is convinced that nerve stretching is an excellent expedient.

CLINICAL EXTENSION.

Another era has been opened this week in the Aural department of the Allgemeinen Krankenhaus. Hitherto, Prof. Politzer's beds have been, since Billroth's time, indiscriminately scattered among the surgical patients, which are forthwith to be isolated and kept quite apart from other surgical cases.

BOYCOTTING THE CHEMISTS.

A feud has broken out between the chemists and the charitable societies of Vienna that has led to the application of "Boycotting" of 105 of the "Wiener Apotheken." Every country has its own peculiar party of pseudophilanthropists who preach and practice charity at another's expense with tyrannical vehemence, and whose contributions to such objects are never discovered. A large charity of this kind, under the name of the "Wiener Genessenschafts-Krankencassen," exists in Vienna for the supply of medical attendance and medicines to the poor, which is none other than the middle-class, at a greatly reduced rate. Before the "Chamber of Medicine" was formed this class was a source of trouble to the medical profession, as many would not listen to their

terms. Since then a tariff has been fixed. Somehow the apothecaries have not yet got a proper fixed understanding about the price of the medicine to be paid by those so-called charitable institutions, which the chemists think are able to pay a better price. On this account the charity has issued a ban under the heading of "Boycot" against 108 of these uncharitable unbending chemists.

The Operating Theatres.

GUY'S HOSPITAL.

INTRODUCTION OF BONE FOR THE RESTORATION OF AN OLD COMMINUTED FRACTURE OF THE TIBIA .-- Mr. ABBUTHNOT LANE operated on a girl, æt. 14, who, when 18 months old, sustained a fracture of the tibia, which did not unite. On subsequent occasions the intervening fibrous tissue and the adjacent ends of the tibia had been removed, with the idea of establishing union between the raw surfaces of bone. At the present time, however, the foot was almost useless, being displaced inwards, owing to the upward and outward inclination of the lower fragment of the tibia. Both ends of the tibia were separated from one another by a considerable interval, with no connection between them. Mr. Lane cut down on the fragments and cleared them from the adjacent soft structures, and was then able to restore the lower fragment of the tibia to its normal relationship with the fibula, and to render its axis continuous with that of the upper fragment. While they were retained in this position to one another a rabbit was killed, its femurs removed, and their ends trimmed; they were then laced by means of silver wire to the tibial fragments so as to keep them apart and continuous with one another. On relaxing traction on the foot and lower fragment, the interposed bones were found to serve this purpose in a perfect manner. The external wound was then closed and the leg immobilised in a suitable apparatus. Mr. Lane said he did not think it would be advisable for the patient to transmit his weight through the part for at least a year. He considered the important points in the introduction of a considerable quantity of bone were: the absolute immobilisation of the graft, and that a sufficient interval of time should elapse between the operation and any attempt to make use of the part; the length of this interval would vary with the age of the patient, the quantity of bone introduced, the security of its attachment, and the amount of force it would be required to transmit.

OPERATION IN A CASE OF SO-CALLED POTT'S FRACTURE. The same surgeon operated on a nurse, æt. 42, who exhibited the fracture of the fibula and displacement of the foot that results from fercible abduction, which is called, as Mr. Lane remarked, by the very unscientific and unmeaning term, "Pott's fracture." Being employed in a large general hospital, the patient had had the advantages of the best surgical treatment of the present day; in spite of this, however, the lower fragment of the fibula was ankylosed to the upper so as to form a considerable angle with it; the foot was displaced outwards and a little backwards so that an interval existed between the inner malleolus and the astragalus, and the patient was unable to walk. As she could no longer follow the occupation for which she

had been trained for many years, and upon which she was dependent, it was clear, as Mr. Lane pointed out, that the financial depreciation consequent upon her injury was complete, or, in other words, amounted to 100 per cent. He cut down on the fibular junction and freed the lower fragment from the surrounding soft parts; the junction was cut through obliquely in such a plane as to enable the upper end of the lower fragment to be brought backwards and outwards, while the outer malleolus was made to move forwards and inwards, this fragment being rotated round a fulcrum formed by the inferior tibiofibular ligaments; in this manner the astragalus was brought into its normal relationship with the inner malleolus, and the foot with that of the leg; the fragments were wired securely together in this position. Mr. Lane said this formed one of the innumerable instances showing the impossibility of replacing the fragments of the fibula in accurate apposition by any form of manipulation when they had been displaced by excessive and forcible abduction, even when the tibia was uninjured He hoped that the time would soon come when surgeons would display a little more intelligence in the treatment of these conditions, and a little more scientific accuracy in their statements. They seemed at the present time, he said, distressingly anxious to bolster up the absurd idea that it is possible by abduction of the foot to so exert force upon the lower malleolus as to bring the upper end of the lower fragment into the lower end of the apposition with when there existed no such mechanism by means which this could be effected. They could hardly realise, he thought, that the treatment they had adopted all their lives was an absurdity, and they would conceive any statement to the contrary a reflection on their intelligence. He showed another case of so-called Pott's fracture in a young artilleryman, æt. 24, in whom the fibula had been fractured about an inchand a half above the tibio-fibular articulation, and the inner malleolus had been broken transversely midway between its base and summit. It occurred through his having been thrown off the limber of a gun in June, 1898. He was invalided out of the service in January. 1899, as being physica'ly unfit to follow his duty. At the present moment he was unable to follow any employment because of the pain he suffers in his foot and ankle when he walks. The foot is displaced outwards. The fragment of the inner malleolus has followed the astragalus, and has united to the tibia in this abnormal relationship. The fibular fragments formed the usual angle with one another. Here, Mr. Lane said, was a man who was obliged to give up the employment by which he earned his living, and eight months after he had sustained his injury he was so much incapacitated as to be unable to follow any employment other than sedentary, and for this kind of work he was quite unprepared by any previous training. His financial depreciation then was obviously complete, and he was prepared to submit to any operation which would afford him some chance of obtaining a livelihood by relieving some of his present physical disability. Mr. Lane purposed cutting away the malleolar fragment from the tibia, dividing the fibular junction in a suitable plane, and restoring as far as possible the astragalus to its normal relationship with these bones. How different, he remarked, would have been the condition of these two patients if the fragments had been exposed and fitted

Digitized by GOOGLE

accurately together at the time of the injury. Their mechanics would have been as perfect after the injury as they were before.

THE INEBRIATES' ACT.

THERE can be no doubt that by the Inebriates' Act passed last year, and coming into force within a few weeks, a great advance has been inaugurated in the attitude of the Legislature towards the alcoholic habit. In other words, the Government has formally recognised and acted upon the principle that chronic alcoholism is the symptom of some deep underlying condition of the individual, and is not a mere criminal lapse from moral standards, as laid down by the wisdom of Parliament. For our own part, we consider that a fraudulent company promoter is infinitely more deserving of punishment than the habitual drunkard who simply soaks gin until reason is in abeyance and then commits a technical breach of the law. Yet the one lives in secure millionaire affluence while the other registers by the hundreds his appearances in the police court and his sojournings in prison. But while recognising as a profession that a vast concession has been made to medical science in thus treating chronic inebriety as a disease, it is nevertheless important to keep in mind other issues that are involved in the administration of the Act. The Departmental Committee appointed to advise on the subject of the Act has issued a blue book, in which they deal among other matters, with three classes of institutions, namely, (1), State inebriate reformatories; (2), certified inebriate reformatories; (3), private retreats must be borne in mind that inmates of inebriate refor- such as three, six, or nine months almost

matories will require efficient medical supervision, and for an institution of any size it is of the greatest importance that the Superintendent should be a thoroughly competent medical man. That is a point which will be emphatically endorsed by all who have had any acquaintance—and what medical practitioner has not?-with the complex is ues involved in the practical treatment of alcoholism. It may almost be said, indeed, that the medical man who has acquired proficiency in that particular point has approached the acme of professional skill, and we trust that many of these important posts under the Act, so fraught with potential benefits to the community, may be placed in the hands of the profession that by training and temperament is best fitted to discharge them to advantage. Then the Committee make the obvious remark that the whole scheme of the treatment of inmates should be based on the principle that they are detained for reformation, and not for punishment. Towards that principle alike should be directed the dieting, the discipline, the religious and moral training, and even the forced labour. The improvement of the impaired physical condition, the inculcation of regular and industrious habits, the occupation of the mind by a constant round of duties, and reasonable recreation carried on in intercourse with their fellows, which should be as unrestricted, and, therefore, as cheerful as discipline allows, and would be the chief factors in rousing the lost self-respect and sharpening the blunted conscience of the inmates. Every inmate should be encouraged to exercise his faculties and employ his time as remuneratively as possible. He should therefore be employed in that kind of work for which his training and capacity suited him, no matter what that work might be, provided it could be exercised and supervised in the reformatory without serious inconvenience. All that commentary reads admirably and speaks well for the rational and thorough administration of the new Act from the curative standpoint. There are other important elements involved, as already hinted, and these it will be well to consider briefly, or else it seems not altogether improbable that for the short punitive sentence of imprisonment hitherto passed on the drunkard we may find suddenly substituted long terms of what practically amounts to imprisonment under another name-With regard to chronic inebriates there appears to be little objection to bringing them under such a provision, for as the Home Secretary has pointed out in a circular letter to the judges: "You will observe that under the Act you have power to order an inebriate qualified thereunder to be detained for as long a period as three years. There would appear to be a consensus of opinion among medical men and others experienced in the treatment of inebriates that in order to give a chance of effectual operation to even the best-designed method of reformatory treatment a considerable period of detention, amounting in most cases to nearly a year, is essential. for inebriates. As regards maintenance, they remark it It is found that detentions for short periods,

invariably prove ineffectual in securing the desired reformation." Agreeing with those propositions one can hardly avoid Sir Matthew Ridley's conclusion that the chronic inebriate should be detained for three years, and we have no more sympathy with him than with any other person of unsound mental calibre. It is quite another thing, however, when we find the power to detain for a similar period any person convicted of drunkenness, for that is how we read the Act. That is to say, an enormous discretionary power has been placed in the hands of magistrates whereby they may arbitrarily shut up citizens for several years in a virtual prison for simple drunkenness, which is in itself not a crime. It is to be hoped that this aspect of the subject, which nearly approaches the liberty of the subject, will be carefully watched by Members of Parliament. There are other details of administration in which the Act may give rise to future difficulty. However, such as it is we accept it with gratitude as an earnest of the more perfectly humane and rational treatment of mental and moral lapses that awaits coming generations. The removal of the present savage and unjust punishment of minor offences that still blots the national record must inevitably be suggested to the thinking man who realises the vast social revolution that is now being effected in regard to the victim of the alcoholic habit.

HISTORY BASED UPON DIET.—I.

Study directed towards the connection between the habits of nations as regards the form in which the food required for their bodily needs was obtained, and the course of the history of the world's peoples, would assuredly bring forth interesting and valuable results if undertaken by a competent authority. The advance along the path of civilisation has apparently been effected by nation after nation in a haphazard manner. Why were the Chaldeans, the Assyrians the Egyptians, the Persians, in turn the progressive and dominant race? How could Greece subdue Persia, Rome, Europe, as then known, and, to come to our own day, how has Great Britain (with the United States) been fitted to found so large an empire, and to spread so large a number of Anglo-Saxons over the globe? Chiefly, we should say, as the result of climatic and dietetic peculiarities. The conquering peoples throughout history have always commenced their successful careers at periods when they were accustomed to simpler food and subjected to greater hardships than the people conquered by them. In turn they, too, having become unable to carry the full cup, have overstepped the limits of simplicity and sapped their powers of endurance, sooner or later falling victims to some nation still in the vigour engendered by natural habits. When the history of man was comparatively short, the predominant races naturally were those inhabiting the warmer climates, the struggle for simple existence and sustenance preventing the tribes in unkindlier regions from becoming their rivals. As, however, the civilisation

of the peoples in the more advanced and warmer countries penetrated even if only slightly into the lands further north, the superior stamina begotten of endurance of hardships and by less artificial foods soon demonstrated its superiority, a sequence of events which history has time after time recorded for our instruction and edification. It may be affirmed that exactly in proportion to the amount of meateaten by civilised nations on the average so the power of the nation grows, not necessarily physically but mentally, and in the nervous control of their physical power. A Chinese coolie fed on rice can undertake a day's work which would appal a British trade's unionist fed on beef and suet pudding. But pit the coolie against the unionist in the power of applying their individual physical powers and the coolie is nowhere, even if the other use his superior mental capacity in various unprofessional directions. How can the predominance of the southern races in earlier times and the equal predominance of the northern nations now-a-days be explained on this theory? Easily enough! It is well known that in warm climates, even what we should regard as a moderate comsumption of meat is deleterious in the long run. Britons in India are advised to abstain from eating much flesh while in that torrid country. We believe that advice to be founded on error, unless they intend to settle down and bring up their family there. The meat-eating Briton in India is usually the healthiest and the most capable of the If, however, he live and die sustained exertion. and his family are brought up there, continued free indulgence in meat foods is apt to be followed by untoward effects, The people of India and similar countries are dominated by the meat-loving Feringhee, largely by reason of that same love of flesh, largely because the continual influx of the healthy beef-eater, and the efflux of those who have indulged in meat quite long enough in a hot climate for their own good, allow of a regular supply of vigorous dominant minds. The citizens of ancient Rome, in the days of her greatest success and might, do not appear to have abstained from flesh, but to have practised moderation. Later on success and luxury led to the consumption of such foods in greater quantities than permissible in such a climate, leading no doubt to increased brilliance intellectually, but also to national decay. The successive rise and fall of the various peoples of Southern Europe, and the gradual superiority over them attained by the northern races, point to much the same conclusion. The necessary stamina, imparted to those who are continually called upon to experience rapid alterations in weather conditions, the possibility of their consuming a greater proportion of meat-foods, have all told in the course of Nature. It seems probable that a native of any country with a moderately cold climate, and who continues his dietetic habits, will, as a rule, exhibit dominant powers over the natives of warm countries in his person, so perhaps his children if they remain resident, but not necessarily in them or their offspring. What

the ultimate result of the peopling of the Southern States of North America with the descendants of Northern as well as of Southern Europe will be is doubtful. But there is no doubt about the change already apparent in the characters and habits of those inhabitants sprung from Northern European stock. If we were inclined to generalise we should hazard the statement that climate per se has little to do with the moulding of the characteristics of a people, save in so far as it accustoms them to endure heat, cold, or rapid changes; but that indirectly the foods found to be most suitable for the maintenance of health under the different climatic conditions exercises all-important influences. The various bodily attributes are not all affected. The more general and simple are usually uninfluenced, the highest and latest acquired profoundly acted upon. Any form of diet found to be most suitable by the natives of a country for their environment, an instinctive selection founded upon personal experiment, will suffice to develope the muscular organs and the power of work to a high degree, will afford valuable information as to the form of diet best suited for work done under the conditions present, and will give an example of what man as an animal requires under these circumstances. But the limitations imposed by natural environment cramp the free development of the higher mental faculties. Whatever the food be, the lower mental properties, such as those of courage, fear, cruelty, love, endurance of pain, &c., may be equally developed; but the higher mental powers, inventiveness, imagination, power of continued organisation, of logic, are deeply influenced.

RELATIVE IMMUNITY AGAINST SMALL-POX.

THE immunity which may be possessed or acquired by individuals against small-pox and other infectious diseases, is of course only a relative expression. The degree of either natural or artificial immunity must vary according to circumstances, that is to say, according to the intensity of the infection to which they are exposed and to their actual state of health. We know that the virulence of pathogenic organisms varies within very wide limits, and it is obvious that a degree of protection which may suffice to safeguard a given subject against the attack of a moderately virulent organism may prove inadequate when he is called upon to withstand the onslaught of one possessed of a much higher degree of diseaseproducing activity. Moreover the fact of residence in a hot climate, or under hygienic or other conditions which favour the evolution of the more virulent organism has been shown of itself to dispose human beings to the particular disease. It follows that the measure of protection which experience has shown to be sufficient in temperate zones may prove less effectual in the tropics for instance. These remarks are suggested by the use which is being made by anti-varcinators of a comparison between the mortality from small-pox among soldiers

in India during the year 1896 and the freedom in this respect of the inhabitants of East London in the latter half of 1898. Special emphasis is not unnaturally laid by the critics on the assertion that soldiers have all been re-vaccinated, while a very large number of persons in East London have probably not even been vaccinated. In making comparisons of this sort the first condition is to establish a parallelism between circumstances as regards time, place, and susceptibility. It is plain that this condition is not fulfilled when a comparison is instituted between England and India, for it is expressly stated in the Army Medical Reports that in each case small-pox was raging in an exceptionally severe form among the civil population, and only those regiments suffered which were in proximity to native bazaars and in more or less intimate relationship with the native population. The fact that there was no small-pox mortality in the East End during the last of 1898 merely shows months absence of contagion, bad sanitation will not of itself determine its appearance and spread. and vice versa, that as small-pox is not a "filth' disease, sanitation alone cannot be expected to keep it out. It is also worth noting in regard to the assertion that "all the men bore marks of previous vaccination," that the report contains no assurance that they had been re-vaccinated. In one case, indeed, it is mentioned that re-vaccination was carried out two days before admission to hospital, but we are told nothing as to the result of the operation, except that the man died of confluent small-pox. As showing the kind of work done in respect of re-vaccination, it is stated that one man had been twice unsuccessfully re-vaccinated, and died of a malignant form of the disease. Looked at from another point of view, it may reasonably be supposed that the large amount of venereal and other disease in the Indian Army must, in the long run, have a prejudicial effect on the physique of the men who are certainly not all "picked men," as is stated; indeed, the difficulty of finding recruits has of late years led to a marked lowering of the standard all round We may point out that in Germany, where efficient revaccination of soldiers has given such brilliant results, in 1897 only twelve men died of small-pox, and these deaths all occurred in proximity to frontiers of countries where vaccination is not compulsory or is not rigidly enforced, and where, in consequence, smallpox exists endemically. This fact bears out the point already mentioned, that the protection afforded by vaccination, though indisputably very great, may not prove equal to all conceivable emergencies, especially if we allow for the difficulty of ensuring that the operation of re-vaccination is always efficiently carried out. Even in the hands of Army Medical officers, something must be allowed for the "personal equation," and this, along with the specially virulent nature of the infection to which the victims were exposed, affords an explanation of the apparent failure in this instance of vaccination to afford the protection which universal experience shows it to confer under what we may call European circumstances.

Motes on Current Topics.

The Regulation of Street Advertisements.

It is not long since that Parliament found it necessary to interfere to prevent the disfigurement of London by sky-signs, but the perverse ingenuity of the advertising fraternity renders further legislation The newest phase of obtrusive street advertisement is the intermittent or flash light method of calling attention to this or that whiskey or soap, and the rapid extension of this unsightly and dangerous method of forced publicity emphasises the urgent necessity for more stringent and more comprehensive regulations in respect of such attempts. We have already called attention to the danger to vehicular and pedestrian traffic of these flash-light advertisements which, moreover, threaten to convert London streets into a more background for ungainly announcements. The alternating glare and comparative obscurity upon which the success of these devices depends creates a state of things which is rapidly becoming absolutely intolerable. In the only too successful endeavour to "eatch the eye," the attention of the pedestrian is involuntarily diverted from the manifold dangers of London traffic, and constitutes a wanton disfigurement of our principal squares and edifices. The grievance has given birth to a "Society for Checking the Abuses of Public Advertising," and the movement has received the general approbation of the Press. Various restrictions are proposed in the direction of establishing a certain correspondence between the size of the letters and the height of the buildings on which they are affixed, with a maximum applicable to all circumstances and conditions. It is, moreover, proposed to prohibit advertisements above a certain level, which would have the advantage of leaving a certain space upon which the eye of the passer-by may repose without being fatigued by the sight of glarish signs. It cannot be objected that the proposed regulations err on the side in the direction of severity, indeed they constitute but a minimum of what is demanded by public opinion.

The Question of Private Slaughter-Houses.

THE question of the abolition of private slaughterhouses in London is at present engaging the attention of the London County Council. The position taken up by the Public Health Committee is, that in the interests of the public only public abattoirs should be allowed, and in support of this view stress is laid upon the law which prevails in this regard on the Continent. The matter, of course, is one which very largely affects the trade of butchers, and great opposition has been shown by the trade to the proposal to deprive them of the right of having private slaughter-houses. But in these days of scientific precision private interests count for nothing when questions of public health are concerned, and in this regard nothing is more certain than that strict supervision is absolutely essential in order to ensure that animals infected

killed for human food. Undeniably, therefore, it must be obvious that the strict supervision necessary could only be properly exercised under a system of public abattoirs, where every perfect appliance would be at hand to prove the suitability or otherwise of meat for human consumption. In the past it has oftentimes been proved, as the reports of the police courts show, that butchers have wilfully offended in attempting to distribute unwholesome meat among their customers, and probably many cases have occurred of this offence which have escaped the arm of the law. The mere knowledge of this fact alone is a strong point in the advocacy of the abolition of private slaughter houses, and thus, the trade notwithstanding, in time we believe the system of public abattoirs must become general in all the large centres of population.

A Modern Greek's Version of Gratitude.

THE Greek Government have issued an official recent report on their war with Turkey, and in the course of the r remarks, they dismiss the subject of the medical relief sent out to them by Great Britain with a curt general reference to red cross work by foreign countries. Now, considering the splendid service that was done there by this country, this savours in no distant degree of rank ingravitude. The Daily Chronicle alone raised a magnificent fund, and despatched to the seat of war an equipment that has probably never been equalled in the annals of red cross history. Amongst other things its X-ray equipment constituted a pioneer essay in modern military surgery, and then, again, its hospitals, with their perfect nursing and aseptic surgery. did yeoman's service at a time of dire national confusion and disorder. However, as the great and good work of the Samaritan is done for its own sake, and not with a view of gaining human applause, it may be surmised that were the Greeks in similar straits to-morrow the sympathies of Great Britain would be just as easily aroused in spite of their present apparent lack of gratitude. One would certainly have looked for a frank and warm-hearted acknowledgment of favours so ungrudgingly bestowed from a nation that undertook one of the most chivalrous wars ever known in the history of the world. But bravery does not spell organisation any more than it connotes gratitude.

Libel Against a Medical Man.

A SOMEWHAT interesting action was won last week by a medical man under the following circumstances: The plaintiff, Dr. T. J. Vallance, who held a number of Poor-law appointments in West Ham, said to bring in £1,200 per annum, sought to recover damages from a meat salesman, named Terrett, for libel. In March last a visiting committee addressed to him certain inquiries as to seven children under his charge. One asked whether a boy of twelve, who had injured his head, should not have a protective pad. To this plaintiff replied, "Yes, send him to Down's. No use to a boy like him; he will want a new one every week." with communicable disease are not allowed to be As to whether another child would not be bene-

fited by being sent to the Ophthalmic Hos-88 an in patient, he answered, might go. Nothing to be done but to take his eye out, or I will do it when I have time." All seven replies were published by defendant as an election placard, and posted throughout the neighbourhood on flaring bills some three feet in length. The defence admitted that the comments complained of exceeded the bounds of fairness, and paid £20 into Court. The jury, however, gave judgment for £150 and costs. This triumphant issue was in no small measure due to the able way in which the Medical Defence Union engineered the case, and adds another to the now familiar illustrations of the absolute desirability of every medical man belonging to that highly organised and capable body. The knowledge of the legal aspects of medical defence is, in itself, a special science, in which Mr. Hempson, the Solicitor of the Union, has become a past master. The case illustrates also the harm that may arise from a too matter of fact way of treating medical matters when dealing with persons outside the profession.

The Surgery of the Kidney.

In discussing the advances that have been effected in the domain of abdominal surgery, we are apt to dwell too exclusively upon the mere gynæcological aspect of the matter. This is unjust to surgeons who have devoted themselves more particularly to the surgery of the kidney, which has already reached a high level of excellence. The formerly painfully hopeless cases of renal lithiasis, followed it may be by impaction of a stone in the urether with consequent hydrorephrosis, are now summarily dealt with, the obstruction removed and the organ restored to its function, if still capable thereof, and if beyond the stage of restoration its removal enables the patient, relieved from actual suffering, to live on with such measure of health and strength as his one remaining kidney will suffice to maintain. That much more obscure affection known to the vulgar as "floating kidney" is also dealt with by an operation entailing a minimum of danger, and if the results are not as uniformly successful as in renal lithiasis this must be attributed to the fact that laxity of attachment of the kidney is often only part of a widespread condition of tissue weakness.

X-Rays in War.

THE X-rays have established their place in almost every branch of practical surgery, but nowhere more conspicuously than in the rough and tumble of warfare. Henceforth the probe is almost, if not quite, needless on the battle-field, to the vast benefit of the patient, who is thus spared the additional risk of the introduction of septic matter and of painful manipulations that were often worse than useless. The method has now been used in at least four campaigns, and a special literature has sprung up round this part of the subject. One interesting case was reported by Major Beevor, R.A.M.C., from the Indian frontier—namely, that of a man shot in the right side of the chest. The bullet

passed through the substance of the liver, in which an open channel was visible. but it could not be detected by probing. As the patientwas not doing well, Major Beevor was asked to apply the Röntgen method, which he did, and was rewarded by finding a round Afridi bullet in the left loin in the region of the spleen. The missile entered near the lower end of the armpit, whence it went through the liver and across the body to the place where it was subsequently found. How it could have taken a track so closely packed with vital organs and not have caused instant death must remain a mystery. The shape of the bullet and the fact that it was driven by poor native powder, doubtless had something to do with the result. At present an unusual amount of activity is being shown by the many makers of Röntgen apparatus, and before the next great fight takes place it is tolerably certain that great strides will have been made in the direction of portability and stability in field medical outfits.

A Point in the Physiology of Vision.

THE paper read before the United Servic: Institute last week upon "The Relation of Persistence of Vision to Modern Rapid Visual Signalling" isdoubtless interesting and important from the author's. -Mr. E. S. Bruce-point of view, but unfortunately he is quite wrong in his deductions. He has invented an apparatus which he calls the aërial graphoscope. the chief principle of which is a narrow lath of wood painted white in front with a grey centre gradually diminishing in shade to white. The lath having been made to revolve rapidly, a small portion of a magiclantern picture is thrown upon it, with the result that the spectator is expected to see the wholepicture before him apparently in space, the explanation given of this being that the retina retains for a short time any impression presented to it; thus the various portions of the picture have not time to fade before the whole has been successively projected on tothe lath. The author also stated that from experiments. with the graphoscope he had found that the same person could have a very different capacity of persistence of vision at different times of the day according to the circumstances under which he was placed, such as, for example, after violent physical exertion. Furthermore, he proceeds to argue that a good army signaller would be one in whom persistence of vision was abnormally low, and he asserted that bodily fatigue tended to prolong persistence which, he believed, also was the tendency in illness. It is, however, obvious that generalisations upon such a complex subject are impossible. In the first place, it would have to be shown that a signaller's vision was perfect and that he had no error of refraction. Next, it is: almost certain that the maintenance or otherwise of a retinal image is merely the result of the retinal circulation. The lower persistence of vision must depend upon the circulation of the blood in the retina for the time being, and according as this is from some cause or other defective, so will the persistence of a retinal image become less and less appreciable, We-

cannot see, therefore, that there is anything in what Mr. Bruce has shown, although, no doubt, he has drawn attention to a subject which hitherto has attracted but little attention.

An Enlightened Board of Guardians.

THE ways of guardians are so often branded by ignorance and arrant selfishness, that it is a pleasure to note a Board rising to a higher recognition of their The Kingston parochial duties and responsibilities. authorities last week decided that "infuture no application would be received from any candidate seeking appointment in the workhouse, or to the workhouse staff, unless proof were forthcoming that he had been previously vaccinated." We have often pointed out that by indirect official pressure an immense deal might be done to ensure the efficient vaccination of a large part of the community. If the Local Government Board, for instance, were to render universal a rule like that passed at Kingston, there would result a standing object-lesson, as well as a practical enforcement of the value of vaccination. Indeed, it seems almost incredible that the central authority have not adopted some such step generally; but, if that were the case, we should hardly find the Kingston Guardians passing a resolution of the kind referred to. The last-mentioned folk were not content with this practical resolution, but they added another praying the Government to repeal their recent Vaccination Act. Her Majesty's Government enforce vaccination in the Army and Navy, and it may well be asked, Why should they not take a similar precaution with regard to Poor-law officials? Their position, however, now that they have admitted the principle of conscientious objection to the multitude, must be somewhat embarrassing. Atkins and his naval cousins must be vaccinated, but the workhouse porters and other officials may do as they like in the matter of self-protection against the most loathsome of diseases.

Sanitation and Salvation Shelters.

THE proverbially slow-going British ways of dealing with fresh social problems have an admirable exemplification in the Salvation shelters. These institutions, founded on a basis partly philanthropic and partly commercial, fall within the category of ordinary dwellings so far as the control of the local sanitary authority is concerned. In other words, the Medical Officer of Health has no right of entry during the night, the time when the shelter is full, but only in the daytime when its inmates are away. It is true that this difficulty can be got over if a nuisance be suspected, but in that case the necessary legal processes demand the expenditure of much time and money, to say nothing of the delay. one considers the nature of the population of these night resorts, the danger of spreading infectious disease, the verminous environment, and the eye to profits which invites overcrowding and uncleanliness, it is simply amazing that no measures have been taken to bring the shelters under control. parallel case of the common lodging-houses, which

are commercial ventures of private persons catering for the casual poor, presents a very different picture, namely, that of stringent, almost harassing, regulation. The whole question of the shelters has been fought out in the South London parish of St. George the Martyr, which seems to be a chosen spot for the solving of difficult but absolutely necessary sanitary problems. In the course of certain legal proceedings undertaken by the authorities of that district, the dictum of the High Courts of Justice was obtained that the Salvation shelters ought clearly to be included within the operation of the Common Lodging Houses Acts.

The New London Polyclinic.

So far as numbers are concerned, the new Polyclinic in London has made an auspicious commencement. Time only can show, however, whether the working of the scheme will prove successful or not-Judging from the proceedings which took place at the first meeting of the Governors of the College, held last week, some of the details of organisation have still to be determined. The meeting, nevertheless, elected the first officers, and the Council transacted other business of importance, among which may be mentioned the acceptance of the proposal that the West London Post-graduate College should be represented by two of its members on the Council, also that two members of the latter should consist of representatives of general practitioners. Council will, therefore, be twenty in number, with Sir William Broadbent as President, six Vice-Presidents. Dr. W. A. Ord as Treasurer, and Dr. Fletcher Little as Honorary Secretary. It is evident from the high position of those who have identified themselves with this movement that a vigorous effort is about to be made to establish a post-graduate centre somewhat in keeping with the needs of the metropolis. Hence. upon these grounds everyone will be wishful to see the new venture prove a success. But everything will depend upon the method of its organisation. If this be faulty nothing but failure will be the result, and as the defunct London Post Graduate course proved a failure, so will the present newly-founded Polyclinic, unless special care be taken to meet the needs of those whose support it seeks to secure.

The Bath Fever Hospital.

THE Bath newspapers have taken our last week's criticisms upon their fever hospital in good part, and we trust that they will now follow up the matter to the end in an impartial spirit worthy of the reputaof their fine old town. There is one point on which the Bath Chronicle, in our opinion, still takes a mistaken attitude—namely, that of the exact relationship of the Medical Officer of Health to the institution. In its issue of February 2nd an editorial paragraph says:—"Dr. Field is the responsible medical man at the Statutory Hospital, not Dr. Symon's deputy!" It then goes on to say that we have been "led to believe" that the latter was the case. Without further parley, we may at once say that statements of that kind made in the columns of the

MEDICAL PRESS AND CIRCULAR are not, as a rule, founded on fancy, but on fact. In support of the particular point in question the editor of the Chronicle may be referred to the official application and order for the admission of the patient to the hospital. The application is a request that the patient be admitted and kept "during such time as the Medical Officer of Health shall deem necessary." This is to be signed by the last-named officer and sent to the matron. We should like a clear and substantiated account of the staff, buildings, organisation, and work of the hospital, say, during the past five years.

A Mere Act of Justice.

Our readers may recollect the regrettable case of Dr. Campbell, the late medical superintendent of the Cumberland County Asylum, whose health broke down shortly before his resignation of the post, and caused him to commit an act which led to policecourt proceedings. Previously to this untoward incident the Cumberland County Council had intimated their intention to confer a superannuation grant of £700 per annum upon their officer, whose long service of thirty-three years in the asylum had throughout given satisfaction to the Lunacy Commissionere. But in view of what afterwards transpired it would seem that some pressure was brought to bear upon the Council, urging them to rescind their former decision. We are glad to note however, that this unjust course has not been adopted although the Council have modified their original intention. Dr. Campbell has now been granted a pension of £350 per annum, instead of £700, and thus by refusing to be coerced into perpetrating an act of injustice, the Cumberland County Council have shown a further proof of their regard for an officer who, till his health failed in their service, had always ably discharged his duties.

International Congress on Tuberculosis.

THE subject of tuberculosis is "booming," and the crusade against the dissemination of the disease is making progress daily. There is, therefore, nothing surprising in the announcement that an International Congress is being organised to meet in Berlin next May, for the purpose of discussing tuberculosis and the best methods for arresting its ravages. In order also to make the meeting as representative as possible foreign Governments will be invited to send delegates. Apparently, however, there is no intention of confining the Congress to members of the medical profession, inasmuch as delegates will be present from trade organisations, insurance institutions, hospitals, and other corporations concerned in the prevention of tuberculosis. Dr. von Leyden is the chief official on the Committee of Organisation, and anyone desirous of being present at the Congress should communicate with him direct.

An Irregular Death Certificate.

AT an inquest held a few days since at Kingstonon-Thames, Mr. Merrick, a local practitioner, was taken to task by the coroner for having certified |

as due to convulsions the death of a child whom he had not seen for four days previously. As the child was found dead in its mother's arms, the appearances not being incompatible with suffocation, it was thought desirable to hold an inquest but the post-mortem examination showed that death was really due to double pneumonia. cannot be too careful in these matters, but on the other hand Mr. Merrick would certainly have exposed himself to much odium had he refused tocertify, and we admit that he found himself in a delicate situation. The best course would obviously have been to communicate with the coroner before issuing the certificate, leaving it to that official to determine whether or not an inquest was indicated.

The Jubilee Hospital Again.

This institution, which has behind it such a lamentable history, is again to the fore with yet another tale of malorganisation and mismanagement. At an inquest held last week by the West London coroner on the body of a man who had fractured hisskull in a street accident it transpired that there was no resident medical officer to attend to patients, the house surgeon living at a quarter-of-an-hour's cabdrive from the hospital. The matron is apparently left in charge, and has to decide whether the case is onerequiring immediate medical treatment, but she is not even in telephonic communication with the medica officers. Slight cases are attended to by the matron and sent away, and she is expected, in the event of an emergency such as sudden hæmorrhage, to apply a tourniquet and send for the doctor who may or may not put in an appearance in about half an hour-Here is a hospital with eight beds left to the mercy of a matron who, whatever her experience and good sense, cannot be expected to fulfil the functions of matron and medical officer rolled into one. Such a truly scandalous condition of things makes one regret that there is not some check upon these private-venture concerns which are labelled hospital, and thereupon tout for the support of the charitable. In any event the police ought to receive instructions not to take the victims of accidents to such an institution, seeing that others, not far distant and admirably equipped, are available.

Boards of Guardians and the Appointment of Vaccination Officers.

THE Local Government Board are having some trouble with certain Boards of Guardians in respect to the appointment of vaccination officers. As is well known, some of these Boards are predominated by anti-vaccinationist faddists, to whom the mere mention of vaccination is as a red rag to a bull. Consequently when the question of appointing a vaccination officer for their respective districts comes up for discussion they are able to carry a resolution refusing to make any such appointment. The Local Government Board, however, have very plainly shown that they will not sanction this nonsensical course of action, and they have insisted upon a vaccination officer being duly

appointed. The Eastbourne Board of Guardians are at present endeavouring to shirk their duty in this respect. But they might as well submit with a good grace without further ado to the inevitable. Perhaps these recalcitrant Boards have overlooked the fact that the central authority can compel them to make the appointments.

The "Grammar School" Science of the London Colleges.

IT will be recollected that the Irish College of Surgeons addressed to the last meeting of the General Medical Council a very emphatic remonstrance against the recent action of the London Conjoint Examination Board, which—in defiance of the resolution of the Council-had intimated that it would accept the Grammar School courses in chemistry, practical chemistry, physics, and biology as part of the requisite five years' course. The Irish College regards such courses, pursued by schoolboys of unknown age, in the int rvals of their Latin grammar and arithmetic, as a transparent sham, and a palpable evasion of the regulations for the medical curriculum. and that College has quite recently refused to recognise such studies in a technical school because it had no assurance of their bona fides. When the protest of the Irish College came before the Council, the representatives of the two London Colleges, seeing that it was backed by the Education Committee, thought it wise to cry peccavi, and the subject was remitted back to that Committee to see what would be done. We observe with satisfaction that the Conjoint Committee has recommended the Colleges to rescind the objectionable announcement, and that the London College of Physicians has assented, though not without opposition from the Grammar School party. The question, however, still remains whether studies supposed to be so pursued in such Institutes can be recognised in any way as part of the medical curriculum.

Doctors' Unqualified Dispensers.

THE question of the employment of unqualified dispensers by medical men has been formally brought before the Pharmaceutical Society by the indefatigable Mr. Glyn Jones, and, on the motion of the President, was referred to the Law and Parliamentary Committee of that body for consideration and report. Threatened people proverbially live long, and in spite of the sensation created by the unfortunate incident, to which we recently called attention, it is quite possible that the humble and unqualified dispenser may outlive his present critics.

The Royal College of Surgeons, Ireland.

THE President and Council of the College have re-elected Sir Philip Smyly as its representative in the General Medical Council for a year from this date. The position was contested, as it was last year, by Dr. Archibald H. Jacob, and, as last year, Sir Philip Smyly was successful by a majority of one. The Council contains twenty members besides the President.

An Australian Abortion Tragedy.

ANOTHER of these too frequent and lamentable abortion tragedies is reported from Melbourne, where Dr. Gaze is reported to have been arrested in connection with the death of a young woman whose body was found floating in a box in the river Yarra, the receptacle having being insufficiently weighted with stones. An examination of the body revealed the existence of pregnancy, together with the presence in the stomach of a large quantity of arsenic.

PERSONAL.

HER MAJESTY THE QUEEN has consented to open the Diamond Jubilee wing of the Royal Isle of Wight Infirmary to-day (Wednesday).

THE Duke and Duchess of York will open, on March 1st, the new wing of the Royal Portsmouth Hospital.

Dr. Roux, chief of the Pasteur Institute at Paris, has been elected a member of the Académie des Sciences, vice M. Aimé Girard, deceased.

WE learn with regret that Dr. William Frazer, of Dublin, F.R.C.S.I., M.R.I.A., is still suffering from the very serious illness which he has had for many weeks. Dr. Frazer is well known as a high authority on antiquarian subjects, and a valued member of the Royal Irish Academy.

SURGEON W. J. MAILLARD, R.N., M.D., V.C., having been awarded the Victoria Cross for bravery during the recent disturbances in Crete, the medical officers of the Mediterranean Fleet entertained him to dinner at the Malta Union Club on bestowal of the honour.

A MEMORIAL to the late Dr. Henry Marshall, of Clifton, consisting of a side altar, which has been erected by subscription in the Lady Chapel of St. Raphael's Church, Bristol, was dedicated a few days since by the Bishop, who spoke of the life and work of Dr. Marshall as a brilliant example to be followed.

PROFESSOR WIGGIN, of the College of Physicians, Chicago, has, according to a telegram in the Morning Leader, been suspended because, in one of his lectures on pathology, he described woman as "a two-legged dyspeptic owl," and said that the "female form divine" was the climax of Nature's irony. Of course, the women's clubs are up in arms at such an insult.

Scotland. [FROM OUR OWN CORRESPONDENT.]

The Late Professor Coats, of Glasgow — Professor Joseph Coats, whose death was recorded in the last issue of this journal, was in many ways a remarkable man. He first distinguished himself as a Glasgow student under the late Professor Allen Thomson, whose method he closely followed and imitated. After graduating in 1867 with "honours," he proceeded to the Continent, studying both in Leipzig and Würzburg under Virchaw. On his return to Glasgow he became house surgeon to Lord Lister (then Mr. Lister), and succeeded the late Dr. Samuel Moore as pathologist to the Royal Infirmary, and from the Royal went over to the Western Infirmary also as pathologist. Even from his early days as pathologist in the Royal Infirmary has pathologist in the Royal Infirmar

tance of a substitute. He, however, seemed to get over these attacks rapidly until while in the Western he had really a severe attack, after which he seemed to age greatly. About eighteen months ago he was seriously ill, and after his partial recovery took a trip to Australia and New Z-aland for the benefit of his health, and on his return seemed greatly benefited by it. Resuming his lectures in due course with great spirit, the students gave him quite an ovation, and it was hoped that he would long be spared to carry on and teach in his lucid and concise manner the subject he loved so well. His health, however, gradually gave way, and, matters becoming serious, it was deemed advisable that an operation should be performed, which was accordingly done on January 21st, when it was discovered that there was a malignant tumour in the splenic arch, which was accordingly removed. All appeared to be going on well when however, he gradually became weaker and died on Jan. 24th. His death is a very heavy blow to the university. After seeing his hopes realized in the establishment of a chair of pathology, chiefly through his own exertion, and occupying the chair as the first professor for the brief period of five years, his untimely death is the more to be deplored. On the day of his funeral, the students through out in large week. funeral the students turned out in large numberto do honour to his memory. Few men, especially in the medical profession, who have lived, worked, suffered and died, have been more beloved than Joseph Coats
THE VACANT CHAIR OF PATHOLOGY.—We understand

that Dr. Lewis R. Sutherland, M.B.C.M., assistant to the late Prof. Coats, is an applicant for the Chair of Pathology now vacant. The patronage is vested in seven curators, of whom four are nominated by the University Council, and three by the directors of the Western Infirmary. The Professor is the pathologist to the Western Infirmary, and the salary attached to the Chair is something like £1,100, and no doubt there will be many applicants for the post, but when it is considered that Dr Sutherland carried on the class for a considerable time, and during all the period when Dr. Coats was on his Australian trip, it is hoped that he will be elected. Certainly he is well qualified; he is painstakin r, obliging, and amiable, a good lecturer, and a general favourite with the students, so much so in fact that if the students had the appointment to confer no other would stand a chance. Unfortunately Dr. Sutherland has been laid aside for some time past, having been suffering from pleurisy. During his temporary absence the lectures have been ably carried on by Dr. Ferguson, another assistant of Professor oats. This gentleman up till Christmas had to do all the work of the Pathology Department singlehanded, besides giving the ectures and demonstrations. We have no hesitation in saying that Drs Sutherland. Both are good lecturers and teachers, qualifications which are not always found together. We understand that the patronage of this chair, now vacant, is in the hands of a Board of Curators, four of whom are appointed by the University Court and these but the say the by the University Court, and three by the managers of the Western Infirmary. The curators met on Thursday afternoon. Present: The Principal (in the chair), Dr. Hector Cameron, Dr. McVail, Mr. J. H. Dickson. Mr. James Boyd, and Mr. William Ker. Instructions were given to advertise the vacancy. Applications to be sent in by March 24th. The new Professor will be required to begin his duties on April 25th.

GLASGOW ROYAL INFIRMARY.—The annual meeting of the Qualified Contributors to the Glasgow Royal Infirmary was held on the 30th ult., the Lord Provost, Sir David Richmond, presiding. We must congratulate those who are immediately concerned in the management of the institution that instead of a few thousands the deficiency for the past year amounts to the small sum of £742 5s. 11d. After compliments were paid all round to everyone in connection with the institution the proposal of females to act on the directorate was brought before the meeting. Mr. Hugh Brown stated that as two of the old directors' term of office had expired it was necessary that two new ones should be elected, and he proposed the names of Mr. Neilson and Mr. Warren. Two ladies were proposed in opposition by Col. Denny, viz, Mrs. Mather and Mrs. Napier. At the end of the voting, which; by the way, was sealed by envelopes, it was found that the

gentlemee candidates were returned by large majorities, Mr. Neilson polling 85 votes and Mr. Warren 83, the ladies polling but 26 votes each

How is it Done?—We are informed by newspaper paragraph, sic—"Forensic Medicine.—Professor Glaister, M.D., F.R.S.E., Regius Professor of Forensic Medicine in Glasgow University, has been appointed one of the Medico-legal Examiners of the City of Glasgow, in place of the late Professor Coats." Is this an advertisement? We hope not! But, how is it that the appointment has been made almost instantly on the demise of the late professor? An instance of a similar nature recurs to our mind where, while attending a professional brother a message was sent to the seat of Government soliciting the dying man's appointment. He obtained the appointment, but latterly died in a lunatic asylum. "Allah is just." How is it that, as we have already spoken, de mortuis nil nisi bonum, yet why so much haste in putting on the dead one's shoes? The late Professor A. S. Simpson was able to prevent an appointment, but in course of time Professor Simpson was gathered unto his fathers, and now his little jokes are retold to a body of students who laugh at them, and without poor "Friday" being present to lead off the laugh. Why are these appointments given to those who already hold either university or hospital appointments? Are there no equally capable men outside the walls? Is influence the only "sesame"? Yet there are two men in Glasgow who rise above the ordinary; they depend upon their own merits, they are now to the front, and long may they remain there, even although the loaves and fishes do not fall to their lot. Brain comes out first. Suum cuique.

DETERMINATION OF SEX IN ECTOPIC GESTATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR. - Now that a very considerable number of cases of extra-uterine gestation have been operated on, would it not be interesting if the sex of the fœtus could be ascertained in such cases?

The pregnancy taking place in Dr. Strauch's seventynine cases (as notified in your last issue) in the proportion of right tube, 31; left tube, 39.

I think the noting of the sex. if only in a proportion of the cases (some, of course, being too young), might help to prove or disprove the old theory of a different sex from each overy.

I am, Sir, yours truly,

Cheltenham.

ALEXANDER DUKE.

MEDICAL AID ASSOCIATIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir,-Of the harm done to the medical profession by these associations there can be no possible difference of opinion. The question is, What measures should be taken to endeavour to prevent men from becoming allied to them? With the competition that now exists in the profession, it is useless to point out to the junior members how undignified it is to ally themselves to a trading concern. Neither will they listen to the counsels of their seniors when it is pointed out to them that the ways of these aid associations are such as respectable friendly societies would not think of adopting. What requires to be done is to prove to them that they will suffer themselves if they become medical officers of them. Once let it be known that medical men holding office under these trading associations are ineligible to become members of the various medical associations and local medical societies, then—and then only—will be there a reasonable prospect of preventing men from becoming allied to these "touting" companies.

I am, Sir, yours truly,

G. P.

Laboratory Aotes.

WE have received from Messrs. Maiche, Ltd., of 4, St. Mary Axe, London, E.C., samples of "Oxydol," an extremely powerful antiseptic. Oxydol is essentially a solution of hydrogen peroxide of great purity, a quality which renders it equally suitable for internal as for external use. When examined in an intrometer by the B.P. test it yielded seven times its volume of gas, and on evaporation it leaves practically no residue (6 grains per gallen). The amount of free acid is very small, being only 0.12 per cent. calculated as hydrochloric

Oxydol is absolutely unirritating, and may be applied without hesitation to freshly wounded surfaces, which it promptly renders aseptic. It inhibits all fermentation, and for this reason is especially recommended for internal administration in gastric disorders, associated with the presence of putrefaction or pathogenic organisms in the alimentary canals. In typhoid fever it deodorises the motions, and notably modifies the painful intestinal symptoms of that disease. It is valuable as a mouth wash and gargle, in that it renders these cavities aseptic, thus averting a fertile source of contagion. It is an excellent gargle, for use in infective sore throat, whether scarlatinal or diphtheritic, as well as in those forms due to other organisms. The importance of local treatment in such a disease as diphtheria is generally recognised, and it must be an advantage to make use of an antiseptic which is non-toxic or non-irritating.

VIBRONA.

Vibrona is a tonic wine with a basis of red cinchona bark, duly standardised in respect of its alkaloidal con-The cinchona constituents are in the form of neutral hydrobromates, a form which is reputed to be free from the inconvenient effects which even small doses of cinchona and its alkaloids produce in certain persons, however administered. Vibrona, with its cinchona basis, is distinctly tonic and recuperative in its action, and must not be classed with wines, of which coca active is the constituent, the effects of the latter drug being of quite a different nature and, if injudiciously or indiscriminately used, very apt to prove detrimental.

In Vibrona we have what Americans call an "ele gant" and highly palatable vinous preparation of cinchona, the value of which is proved by the rapid strides it has made in professional favour.

Medical Rews.

Royal College of Physicians of London.

The second award of the Weber-Parkes prize and medals (to be awarded triennially to the writer of the best essay upon some subject connected with the ætiology, prevention, pathology, or treatment of tuberculosis, especially with reference to pulmonary consumption in man) will be made in made in 1900. The adjudicators have selected as the subject of the essay for that occasion -"The ætiology of human tuberculosis and the assistance which a knowledge of the ætiology may render to the task of prevention." The essay must be based on original work and observations (experimental or other) of the author, and must include a detailed exposition of the methods employed and their mode of application. The value of the prize is 150 guineas and a silver medal. A similar medal, distinguished as the second medal, will be awarded to the essayist who comes next in order of merit. The award will be made on some day previous to October 18th (St. Luke's Day), 1900.

The Medical Sickness and Accident Society.

THE usual monthly meeting of the Medical Sickness, Annuity and Life Assurance Society, was held on 27th ult., at 429, Strand, London, W.C. There were present Dr. de Havilland Hall in the chair, Dr. J. B. Ball, Mr. J. Brindley James, Mr. F. Swinford Edwards, Dr. Walter Smith, Dr. Alfred S. Gubb, Dr. W. Knowsley Sibley, Mr. Edward Bartlett, and Dr. Francis J. Allan. accounts presented showed that, as is usual at this time

of the year, the Society was receiving a considerable number of claims for sickness benefit, but they were for the most part of short duration, and the total amount of sickness experienced is well under what is expected and provided for in the contributions. The committee specially examined into the claims arising from permanent incapacity. In these cases a provision, usually of one hundred guineas a year, is granted to the members, and they are entitled to receive this without deduction until they reach the age of sixty-five, should they live so long. The accounts for 1898 which will be presented to the members in May next, show that the financial position of the Society is very strong. Prospectuses and all particulars from Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London, W.C.

THE MEDICAL PRESS.

Royal College of Physicians, Edinburgh, Royal College of Eurgeons, Edinburgh, and Faculty of Physicians and Surgeons, Gla-gow.

THE Quarterly Evaminations of the above board were held in Edinburgh in January, with the following results :

First Examination, Four Years' Course.—Of 17 can-

didates the following 5 passed the eramination:—
John Lang Niven, Shanghai; Robert Shenton, Derby; Thomas
Lynas, Belfast; Robert Elliott, Manchester, and Samuel Robinson,
Ireland.

First Examination, Five Years' Course,—Of 20 candidates the following 12 passed the examination:—

T J. McKaigney, London erry; James H. Sutherland, Stirling-shire; M. V. Shanakan, Cork; John H. O'Sullivan, Galway; Richard Lewis, Portmadoc; William S. R. Dick, Ballynafic. John W. Cross, Houghton-le-Spring (with distinction); Roger L. Williams, Mountain Ash, South Wales; James A. Whitla, Monaghan; Herbert McMaster, Donaghadee; Henry Doig, Glasgow (with distinction), and Peter Watt. Tinwald, Dumfries.

Second Examination, Four Years' Course.-Of 24 can-

didates, the following 10 passed the examination:—
John Wilson Dickson, Tyrone; Alfred J. W. Noble, Aberdeen; Robert Paterson, Ayrshire; James Ebenezer Boon, Kirkcaldy: William D. Dickson, Co. Tyrone; Barclay B. Head, Kent; Kenneth R. D. Shaw; Edwin Robert Thomas, Dowlais; William Boyd, Kilrea; and Henry John Clague.

Second Examination, Five Years' Course.—Of 30 can-

Second Examination, Five Years' Course.—Of 30 candidates, the following 16 passed the examination:—
Patrick Carroll, Kildowery, Ireland; W. Brown Heagerty, Cork: Ethelbert Hearn, Kent; Angus McInnes, Old Kilpatrick; Haroid W. Young, London; Prederick A. Georgeson, Wick; Frederick C. Willmot, South Africa; John M. Morton, Glasgow (with distinction); James Colquhoun, Durham; William C. M. Burnside, Belfast; Daniel McIntyre, Littleborough; John P. Cameron, Bangalore, India; Kallyani Pado Chatterjee, Calcutta; W. James Healy, New South Wales (with distinction); Anthony Hagarty Corley, Dublin, and John Kean, Newry.

Third Examination, Five Years' Course.—Of 25 Third Examination, Five Years' Course.—Of 25 candidates, the following 15 passed the examination:— John B. Swinden, India; Henry F. Stilwell, England; John Thomson K. Thomson, Glasgow; Frederick W. Tough, Aberdeen; Albert E. Ward, Glasgow; William Airlie Ogilvy, Cambuslang; Philip H. Parsons, Essex; William Donovan, Blarney, Cork; William A Benson, Durham; Edith Anna Wynne-Edwards, Montgomery; Charles R. Sutherland, Durham; William J. Morgan, Wales; Mary Birrell Davies, Liverpool; William A. Dawson, Bandon; and George Evans, County Derry.

Einel Examination, Of 101 candidates the following

Final Examination.—Of 101 candidates the following 53 passed the examination, and were admitted L.R.C.P.E., L.R.C.S.E., L.F.P. and S.G.:-

Joseph P. Woodhouse, Stockport; Arthur Clarence Turner, Copake; Francis C. Gould, Hales Owen; John Hilton Howlett, Norwich; James V. Watson, Darlaston, Staffs; James Ress, Ballymena, Co. Antrim; Thomas L. Wyndham, Surrey; William Lloyd, Carmarthen; Thomas A. Chalmers, Ayrshire; Ellis Owen Jones, Bethesda; Frank Rowland, Birmingham; W. C. E. O'Donoghue, Dublin. Charles Abbott, Leeds; James Fleming, Avondale: John Francis Dwyer, Co. Cork: Jacob M. Wood, York; Ernest Alexander Campbell, Aldershot: Herbert M. Cockeroft, Masham, Yorks: George Yeoman, Osmotherley, Vorks: John Herbert Gibbs, London; Charles F. Graves, London; Edward Lewis Nathanial Hopkins, Carmarthen: Alfred Myles Staunton, Ireland; Mary Ariel Stewart, Portishead; John C. Danaher, Limerick; Michael Halpenny, Ardee; Herbert John Beven, Ceylon; Henry Fowler, London; William Roper, Bridport; W. Marley Cass, Durham: Samuel Rees, Trefrin; Elsie Rosa C Taylor, Tunbridge Wells; F. Morton Black, Broughty Ferry: Thomas Webster Atkins, Cork; John Kerr, Inverness; Frederick P. Walsh, County Cork; Pull J. Van-Coller, Cape Colony; Kristualal Datta, Calcutta; Gervas Parnell, London; Francis Pius Lauder, Bombay; James Barkley, Maghern: Francis Ed. Dowling, Cork; Donald F. Schokman, Colombo, Ceylon; Reginald C. M. Hoare, Birmingham; Caris W. Iliffe, Derby; Andrew F. C. Gilmour, Linlithgow; Edmond Walsh, Limerick; John Timothy Buckley, Ireland; Cyril H. Bürger, Jamacia; Lydia Prio Datt, Nepaul; Timothy J. O'Donovan, County Cork; John Patrick Corcoran, County Mayo; and John G. Blantyre, Gowlland, Sydney.

FOR THE AMUSEMENT OF PATIENTS-

A CORRESPONDENT sends us the following efficion:—During the period of convalescence it is sometimes a difficult matter for the practitioner to propose a form of amusement suitable to the patient' class of illness. I venture to suggest the following as a help in the complaints indicated:—

Nap. Hide and-Seek. Billiards (spot barred). Leap-frog.
The Race Game. Draughts. Rubber of Whist. Cricket. Puss (pus) in the Corner.
A. D.

STATISTICIAN.—We have succeeded in finding the formula you require, though not without difficulty. M. de Movine, in 1885, described his method as follows:—When it is desired to estimate the "expectation of life" for a person at a given age, he directs us to subtract the actual age from the number 36, halve the remainder, and the result is the "expectation of the individual." Thus with a man, set. 42, 86 minus 42 equals 44 divided by 2 equals 22. equals 22.

A WONDERFUL OPERATION.

"YES, sir." said the American surgeon, "I have performed some wonderful operations. Perhaps the most surprising and most successful was after a railway accident. One of our prominent citizens was absolutely disembowelled by a fragment of the car I was on the spot. There were some sheep grazing near by, and in a moment's time I had transferred the inside of one of those sheep to the palpitating form of the man and sewed him up."

"That m n recovered, sir?" "Yes, sir; and he had lambs in the pring."—Exchange.

CRANE. - On Jan. 25th, at Kensington Court Gardens, Samuel Leonard Crane, C.M.G., M.D.
FISHER—On Jan. 30th. at hts residence, Lowther Terrace, Lytham, Luke Fisher, M.D., aged 59 years.
LLES. - On Jan. 31st., at his residence, The Retreat, Fairford, after a brief illness, Uaniel Hes, M.R.C.S., aged 57.
PAUL.—On Jan. 29th, at The Terrace, Camberwell, John Hayball Paul, aged 83 years
TURNER.—On Feb 2nd, at 24, South Street. Greenwich, Reuben Turner, L.R.C.P.I.. L.R.O.S.I., son of the late S. J. Turner, J.P., Dundalk, aged 44.

CODINAMEROLL

ALLEN & HANBURYS

PECIAL COURT LOMB ARD ST

Allen & Hanburys' "Perfected" Cod Oil

S prepared at their own factories in Lofoden and Sondmor, in Norway, from absolutely fresh and selected livers of the Cod-fish only, all stale livers being rejected. In stormy weather the fishing boats are often delayed, the fish being landed in a state of partial decomposition. This, together with the fact that manufacturers are frequently not careful to use only Cod

livers, results in the Oil being of varying composition and contaminated with bye-products nauseous to the taste, indigestible, and irritating to the stomach.

By the special processes employed the elimination of all nauseous oxidation products is effected without impairing in the smallest degree the invaluable nutritive and medicinal properties. By a very recent modification of our methods the "PERFECTED" Oil is now rendered freer from taste than at any period since its introduction to the Profession in 1879, when the British Medical Journal described it as having "almost the delicacy of Salad Oil," and the Lancet as being "as nearly free from taste as Cod-liver Oil can be."

Being easily borne and assimilated where ordinary Cod-liver Oil is refused, it is, for these and the above reasons, the most efficacious kind in use.

"It is a great boon to get such an Oil." | "No nauseous eructations follow after it is swallowed."—Med. Press & Circular.

In the "PERFECTED" Oil we have a food which can be easily digested, even in cases of Phthisical Dyspepsia, where Cod-liver Oil is specially indicated, yet cannot be borne.

ALLEN & HANBURYS desire to state, as emphatically as possible, that their "PERFECTED" Cod-liver Oil is NEVER supplied in bulk to be bottled by retail dealers, and that no Cod-liver Oil represented as being their "Perfected" is genuine unless sold in their original capsuled bottles and bearing their Signature in white across the label, and their Trade Mark—a Plough. Frequent misrepresentations have involved disappointment both to doctor and patient, and necessitated legal proceedings against the wender.

REPORT

On an Exact Bacteriological Investigation made to ascertain the Value of

"Sanitas" Fluid, "Sanitas"

As DISINFECTANTS for GENERAL USE,

By C. G. MOOR, M.A. (Cantab.), F.I.C., F.C.S.,

Member of the Society of Public Analysts, Joint Author of "Applied Bacteriology," &c., &c.

C. T. KINGZETT, Esq., F.I.C., F.C.S.,

THE "SANITAS" COMPANY, LIMITED,

BETHNAL GREEN, LONDON, E.

BETHNAL GREEN, LONDON, E.

DEAR SIR,

I beg to present you my report on the experimental investigations I have conducted on the preparations manutactured by your firm, named "Sanitas" Oil, "Sanitas" Emulsion, and "Sanitas" Fluid.

The experiments were made to ascertain and establish, if possible, on a scientific basis, the efficiency of these preparations, and their suitability for the purposes for which they are designed as indicated by your publications and labels giving directions for use.

The experiments instituted for this purpose were as follows:—

(a) In the case of the preparations above mentioned, various disease organisms—namely, those of Anthrax, Cholera, Diphtheria, Staphylococcus Pyogenes Aureus and Typhold were brought into contact with the disinfectant for a given time and in a manner detailed below, and means were taken to ascertain whether the disinfectant employed was sufficiently powerful to determine the death of the organism in a given time.

(b) A second series of experiments was undertaken to ascertain the effect when similar cultures were exposed to different strengths of these disinfectants for a standard time.

(c) Experiments were also made to ascertain the effect on ordinary air, as regards the removal or extermination of organisms suspended in it, by spraying with "Sanitas" Oil and "Sanitas" Fluid.

(b) In the case of "Sanitas" Oil, I have experimented as to the article of the versely the of the versely

"Sanitas" Fluid.
(b) In the case of "Sanitas" Oil, I have experimented as to the action of the vapour given off at a temperature not exceeding that of the human body.
(e) Finally, I have tried some experiments to ascertain the action of "Sanitas" Oil and "Sanitas" Fluid on the Bacillus of

TABLE 1.

EXPERIMENTS WITH "SANITAS" OIL.

Silk threads infected with cultures of the following organisms were exposed in "SANITAS" OIL for the times shown below and then incubated in broth. Growth is shown by a + sign, no growth by a · sign.

Controls all grew well.

I next proceeded to ascertain the strengths of these disinfectants

I next proceeded to ascertain the strengths of these disinfectants required to ensure the death of the above-named bacteria in a given time—and in the following experiments the time of exposure of the facteria to the action of the disinfectant was in all cases ten minutes. In these experiments I used the method of shaking together an 16 ively growing broth culture of the organism to be tested, with such a quantity of disinfectant that the resulting mixture contained the tringth of disinfectant specified in the tables below; the exact details of the method of experiment are described in Pearmain & Moor's Ap. lid Bacteriology, 2nd Edition, pages 377-382. (Balliere, Tindall, ap. Cox).

TABLE 3.

"SANITAS OIL.—As the Oil is not readily miscible with water the "Sanitas" Emulsion, which contains 45 per cent. of "Sanitas" Oil, was employed.

Anthrax and S. P. Aureus were also both destroyed by the 50 % mixture in ten minutes' exposure.

Controls all grew well

(i). I have made several experiments as to the destruction of bacteria floating in the air of a room by spraying the air with "Sanitas" Oil, and with "Sanitas" Fluid—testing the air by means of Hesse's tube.

The removal of bacteria from air by spraying will, doubtless, depend very greatly on the mechanical action of the particles of spray, because, as is well known, bacteria are very largely removed from air by a shower of rain, therefore, too much importance must not be attached

shower of rain, therefore, too much importance must not be attached to such experiments.

Taking, however, the mean of several experiments, whereas the air of the room contained a considerable number of bacteria before spraying, the numbers were reduced, after spraying, to under five per cent. of those previously found.

(6). "Sanitas" Fluid floes not give off much vapour at ordinary temperatures; but, Sanitas" Oil, on the other hand, is sensibly volatile at room temperature, and I have tested the action of the vapour given off by "Sanitas" Oil, at blood-heat on bacteria similar to those used in the broth and thread experiments.

Some of the growth from agar tubes was smage on filter-paper and suspended in a wide-mouthed jar containing a little "Sanitas" Oil. The whole was placed in the incubator (37° C.), and, after an hour, cultures were made on to nutrient media. The result was that only the two most resistant organisms—namely, Anthrax and Staphylolocus Pyogenes aureus—had survived, while Cholera, Diphtheria, and Typhoid failed to grow.

(7). Having a culture of Bubonic Plague brought by a student from

(7). Having a culture of Bubonic Plague brought by a student from Hong-Kong I tried the effect of "Sanitas" Fluid and "Sanitas" Oil on it. The bacillus was killed in each case by a ten minutes' exposure to a strength of 33 per cent. of each disinfectant—the only strength tested.

tested.

In conclusion, I regard the results of my investigation as affording ample evidence that the "Sanitas" preparations are thoroughly re lable, when employed in the strengths and for the purposes specified in the directions issued by the proprietors, while their non-poisonous nature and pleasant character render them applicable in many instances where such substances as carbolic acid or mercurial chloride would be inadmissible or dangerous.

Paris Clinical Lectures. INFANTILE PNEUMONIA.

By Professor COMBY, Trousseau Hospital.

[FROM OUR OWN CORRESPONDENT.]

FIBRINOUS or lobar pneumonia is very common in childhood, especially after the second year, and it would be well to decide on the treatment to be prescribed. For that, however, it is absolutely ne essary to understand the natural evolution of the malady.

Since the researches of Talamon, Fraenkel. Weich. selbaum, &c., it is generally admitted that idiopathic pneumonia is an infection due to the presence of an encapsuled diplococcus called pneumococcus. This microbe is, indeed, common enough, as it is frequently found in the mouths of healthy persons, though it usually confines its attacks to the lungs. But its field of action is not necessarily confined to the pulmonary parenchyma; it can invade the pleura, the meninges, the peritoneum, &c. These abnormal localisations, with their multiplied and extended points of infection, materially influence the prognosis, rendering it peculiarly grave in almost every case. Apart from these complications recovery is the rule. Of 150 cases of lobar pneumonia treated in my wards during the last eighteen months, I only lost one patient and here the pneumonia was double, complicated with empyema and suppuration of the mas-toid. Out of 202 cases, Rilliet and Barthez reported but two deaths; and Cadet de Gassicourt, one out of seventy patients. From the statistics published by both home and foreign physicians, it clearly results that idiopathic pneumonia is absolutely benign in children, and this benignity contrasts with the gravity of broncho-pneumonia which has nothing in common however with the name of the malady we are treating. The evolution of pneumonia is absolutely cyclic; it commences suddenly, runs its course rapidly, and terminates suddenly; the defervescence sets in as quickly as the invasion, and in a few days the most alarming symptoms give place to all the attributes of health. The cycle generally lasts one week, but it may be shorter (abortive) or longer (prolonged pneumonia). Sometimes the symptoms are well marked, at others insidious and attenuated in their expression; as in the rudimentary pneumonia of d'Espine.

It must be borne in mind that no matter what kind of pneumonia you are called on to treat, the thermic cycle is inflexible, no therapeutic agent can cut it short. It is possible that the natural course of the d sease could be interrupted by a specific remedy, an anti-pneumococcic serum for instance, but this specific we do not possess yet, and we must be modest as to our rôle in the treatment of pneumonia, and spare the patient that injurious medication so justly criti-

cised by Talamon. In the review of remedies appropriate in pneumonia, I will dwell as much on those to be avoided as on those to be prescribed. Where the malady runs

its course without any alarming symptoms, the treatment must be of the simplest, vigilant observation

being all that will be required.

The little patient should be kept in a large welllighted and well-aired room, and the windows opened now and again to change the air. Where the room. on the contrary, is small and dark, inhalations of oxygen may be ordered, with benefit. The temperature of the apartment should be moderate (68 degs. F.); cleanliness of the body is not less necessary, and can be secured by a bath which may be renewed once or twice during the malady, antiseptic sponging (boric acid) of the mouth, the nostrils and the throat should be done systematically, so as to ward off as much as possible secondary infection. The diet should be liquid, and the child will be pressed to drink plenty of bland infusions, so as to provoke renal activity, by which the organic waste and the toxins which threaten to poison the patient are removed; the intestines, moreover, should be attended to, as constipation is very general in pneumonia.

No. 7.

Up to the present I have not spoken of the rapeutical agents; they might, indeed, often be dispensed with In what cases then may they be altogether. prescribed?

Formerly, no case of pneumonia was treated without energetic revulsives and the youngest children did not escape the blister. This revulsive may in some cases be prescribed with benefit as a local derivative, but in the child it is never indicated and may do a great deal of harm. I never prescribe it in pneumonia; it is inefficacious and dangerous, and that is enough to exclude it from our treatment. But if we abstain from the blister, we may with much advantage employ other agents, such as the mustard poultice, dry cupping, local applications of cold water or even ice. I have already said that liquids should be given freely to the patient so as to provoke an abundant flow of urine. It is necessary also to purge once or twice during the disease with castor oil or scammony. If the tongue be loaded and the case complicated with intense dyspnæa and bronchial catarrh, I always order an emetic consisting of a tenth of a grain of tartar emetic and twenty grains of sulphate of soda for each year of the patient; for instance, for a child of ten I give:-

Tartar emetic, 1 grain; Sulphate of soda, 3iij; Syrup of gum, 3j;

Water, 3iij.
a third part to be taken every half-hour in the morning fasting. The patient will thus vomit and be purged three or four times, and a considerable improvement is always the result of this treatment.

The fever runs very high in cases of pneumonia, but it is well known that children bear a high temperature very well. The antithermics, quinine, antipyrin, &c., are of no use unless given in large, that is to say, toxic doses. Cold water acts better and costs less. I have noticed that the cold bath (75 degs. to 65 degs.) was well supported by children, and when resorted to every three or four hours, it lowered the temperature, attenuated the dyspnæa, improved the pulse, and calmed any agitation, delirium or sleeplessness, that might exist. In cases where the malady is complicated with nervous manifestations, such as convulsions, I have found trional to be of great service in five or ten grain doses according to the

age, repeated two or three times a day; where the heart showed signs of weakness moderate doses of digitalis might be useful, say, from one to four grains of the powdered leaves infused in a glass of water and

drunk in divided doses during the day.

You will see by this rapid resume what a small place is occupied by drugs in the treatment of infantile pneumonia. In every case therapeutical hygiene is absolutely necessary; in some cases only, and according to the symptoms, light revulsives, laxatives, cold baths, tonics, and sedatives may be prescribed.

Original Communications.

SOME RESULTS OF OPERATIONS FOR ENLARGED PROSTATE. (a)

By JOHN R. LUNN,

Medical Superintendent, Marylebone Infirmary.

In the Lancet of October 3rd, 1896, a most successful case was reported by Mr. Arthur Hunt, in which double castration was performed on a man, æt. 73, for severe cystitis and enlarged prostate with recovery, after which the patient was able to go shooting and fishing in Scotland. After reading Mr. Hunt's article I determined to do something for my distressing cases of enlarged prostate. This is my reason for bringing a few of my notes before this Society on some of the results of operations for en-

larged prostate.

CASE I.—Edward H—, æt. 72, was admitted into St. Marylebone Infirmary, May 5th, 1896, with an old irreducible hernia on the right side, and retention of urine, for which he had been admitted into the infirmary several times and treated. He stated he was in the habit of passing his water 20 or more times in the twenty-four hours. It was found the retention of his urine was clearly due to an enlarged prostate, the urine was acid 1025 and contained blood. On May 14th, 1896, the left vas deferens and nerves were divided and tied. As no apparent diminution of prostate, and no alteration of micturition had taken place, the right testicle was removed and a radical cure for the right inguinal hernia performed. The operation was perfectly satisfactory, the patient's general health began to improve, though he got retention, but no cystitis, which he had when admitted into the infirmary on other occasions. Taking into consideration the patient's good health and the fact that but for the frequency of micturition, he might be up and a rout, and able to do some light work, he was advised to have the left testicle removed, to which he readily consented. On August 7th, 1897, the left testicle was removed, which did not appear much atrophied. Whilst the patient was under chloroform a careful examination of the prostate per rectum was made, and there was no doubt that though still large and there was no doubt that though still large the right lobe was less prominent than the left, and a large size No. 10 catheter could be passed easily. On March 20th, 1898, the patient said he had kept a record of the number of times he had passed urine in the twenty-four hours, and he said that there was a considerable improvement, since the last operation, he only passed urine ten times instead of sixteen to twenty in the twenty-four hours. He never had now to pass a catheter, and did not get retention and enjoyed life more than he did before the operation. Towards November 29th he developed dropsy, and died December 21st, &c.

Case II.—Edwin H—, et. 63, a hawker by trade, and a married man, was admitted March 4th, 1897.

(a) Abstract of paper read at the meeting of the Clinical Society of London, February 10th, 1899.

He was admitted the first time in February 1896, when he had retention, and the first thing he noticed wrong was an increased frequency of micturition, and he passed water as many as six times every three hours both during the day and night. He stated he used to get very ill with shivering fits, and was obliged to run to the nearest hospital and have his urine drawn off. When he was first admitted it was noticed he had a large prostate, and No. 6 gum elastic catheter was passed with difficulty, the urine then was offensive, and contained albumen, specific gravity 1020, alkaline. Section of the right vas deferens was performed February, 1897, and had a marvellous effect on reducing the number of times of micturition per day. After he had left the infirmary several months, the shivers, as he described it, came on again, though he kept at his work. He frequently got retention, and had to visit the hospital again when this occurred. On May 4th, 1897, he was readmitted to St. Marylebone Infirmary, and with rest in bed, hot baths, &c., he improved in health, his temperature became normal, but still he had to pass his urine several times during the night. He wished for another operation on the other side, so on June 17th, 1897, the left vas deferens and nerves. were tied under chloroform. The prostate had not apparently altered mach in size, though it felt soft to touch. The patient's wound healed by primary union. A month after the operation the patient said he was much better with his urine, and only made water four to six times in the twenty-four hours, and went the whole night without passing his urine. He discharged himself six weeks after the operation in perfeet health, and the urine was quite normal, and he expressed himself much pleased with the results of the operation.

CASE III.—Henry C—, æt. 63, a painter. was admitted into St. Marylebone Infirmary, Dec. 9th, 1896, for double tuberculous disease of his testicles, the right epididymus was enlarged and indurated, and the thickening of the vas extended up the cord on both sides as far as the external rings. On Jan. 4th, 1897, the left testicle was removed. An examination was made of the prostate, which was much enlarged and easily felt. Two weeks after the first castration, the right testicle was removed, after which his general condition began to improve, his appetite increased, his temperature went down, and he expressed himself feeling much better since the operations. The interesting point was the remarkable condition of the man's prostate when examined per rectum, with a No. 10 catheter in the bladder (on June 5th, 1897), one was at once struck with the small size of the gland; in fact, it seemed as though there was a depression at the point where the prostate should have been. The patient got quite well, and discharged himself. I have seen him since, and the urine is normal, and he has no frequency of micturition and otherwise is in good health.

Case IV.—Samuel G—, et. 66, was admitted March 10th, 1897, with retention of urine. No catheter could be passed, even under anæsthetics, and as the patient appeared very ill—temperature, 102·4—the bladder was drained supra-pubically. After a few days the stricture was divided, and a large catheter (No. 10) was passed. The prostate was found to be much enlarged on digital examination, and the catheter was not fastened into the bladder as the urine was very alkaline sp. g. 1020 and offensive, and contained blood, pus, and albumen. The bladder was washed out once or twice daily with lotio boracis, but he did not improve. The operation for castration was suggested, which he refused. His general condition and health began to fail and the man became very ill indeed, and he could only pass a very smal quantity of urine at a time, which was very offensive

Digitized by Google

he became hectic and his temperature rose to 103, and he had rigors with a furred tongue. On May 6th he had begged for something to be done (after being told his case was hopeless). Double castration was performed by the median incision as rapidly as possible whilst the patient was under the influence of A.C.E. mixture. He had a good deal of shock after the operation. The next day the patient expressed himself feeling very much better. He had some incontinence of urine, the temperature became normal in a remarkable way, and the condition of his urine improved, the pus became less, his appetite became ravenous. He then passed 30 ozs. to 40 ozs. of urine in the twenty-four hours without difficulty, and the catheter was only passed twice a week. He began to take Didymin tablets once a day for some weeks, and they were increased to twice a day. The patient began to improve in a miraculous way until August 12th, when he had gained a stone in weight, and was getting up all day and thinking about going out to his work. The urine then only contained a trace of albumin, and was neutral to test paper. He was suddenly seized with vomiting and diarrhoea. and obliged to take to his bed again. The tablets of Didymin were stopped, and he began to improve until November, 1897, when he became ill again with vomiting and uncontrollable diarrhea, the pus in urine increased again, he became semicomatose, and died November 6th, 1897, six and a half months after the double castration.

P.M.—Most of the viscera were in good condition, the bladder was hypertrophied, and contained about one ounce of clear fluid, and cone muco-pus. The orifice of the urethral was quite freely open. The ureters were both dilated and pouched, and contained all the pus. The prostate was not apparently enlarged, but had a very prominent hard middle lobe.

enlarged, but had a very prominent hard middle lobe.

CASE V.—Edwin S.—, et. 76, a joiner, was admitted Jan. 20th, 1898, with retention of urine for which he had been admitted before and was obliged to pass a catheter very often for himself, and complained also of frequent micturition day and night (sometimes getting up at nights 6 or 7 times). The patient's general health was good. On examination of the prostate by the rectum and catheter in the bladder, a large projection could be felt in the rectum the size of a small tangerine orange which impeded the passing of the catheter. He had no hæmaturia or offensive cystitis, the urine was acid and contained albumin. The man stated he passed urine about 16 to 20 times in the 24 hours. On April 29th the left was and nerves were tied and cut under the influence of 10 p c. cocaine which was injected into the tissues where the vas was resected. The wound healed well and was dressed on the sixth day when the stitches were all removed. No improvement of micturition took place, so on June 18th the right vas was tied under the influence of 5 p. c. cocaine, which was injected as before, there was little or no pain from the skin incision, but on separating and tying the cord and nerves with silk gut ligatures, the patient complained of a little smarting pain. On June 30th it was noted the patient got up and expressed himself much pleased with the results of the operation, as he passed good nights and never got retention, and only passed urine half the number of times he did before the operation, and was able to get about as well as ever he did. In the middle of November he began to vomit and become jaundiced and developed cancer of the liver, from which he died on December 18th, 1898. Both testicles were found atrophied, and he had developed a double hydrocele of his tunica vaginalis. His other viscera were normal.

CASE VI.—Thomas P.—, set. 64, a coachman, with a very good history, was admitted in Oct., 1898, with retention of urine, and though a No. 10 catheter could

be passed fairly easily, there was a distinct obstruction about the prostatic part of the urethra, which could easily be felt with the finger in the rectum, the urine was 1.005 alkaline and contained albumin, and he had several severe attacks of hæmaturia after admission. On November 28th double vasectomy was performed under the influence of chloroform. The next day the urine contained more albumin and some blood. He was able to pass his urine normally, and he did not seem any the worse for the operation, and was about the ward as usual. December 30th, 1898.—He tells me he sleeps all night without passing urine, and expresses himself quite well, and was discharged quite well January 6th, 1899.

The Lettsomian Lecture

SOME OF THE CLINICAL ASPECTS OF GRANULAR KIDNEY. (a)

By SAMUEL WEST, M.D., F.R.C.P.,

Assistant Physician, St. Bartholomew's Hospital; Senior Physician Royal Free Hospital, &c.

Granular kidney is a disease of great importance on account of its frequency, a frequency which is by no means adequately recognised. Post-mortem it is often discovered when not suspected. It is often in itself the cause of death, even of sudden death, and it often explains why death has happened in other diseases which otherwise might not have proved fatal. During life it is often discovered unexpectedly if looked for; it is often overlooked if not suspected, and it often explains a case which has been a puzzle until granular kidney gave the key. For all these reasons, granular kidney is not only one of the most interesting of diseases but also one of the most important. The general frequency of granular kidney post-mortem ranges from 11 8 to 18 per cent., so that it is a very common condition.

Nothing will better prove the importance of granular kidney than the following statistics obtained for me by Dr. Horder, the result of an investigation made into the causes of death in persons brought into St. Bartholomew's, dead or dying. The total number of such cases (excluding children under five) was 79, in all of which a post-mortem examination was made. Of these, sixty-four were dead on reaching the hospital, and fifteen died in the surgery. In 48 per cent of these cases chronic interstital nephritis was present; in 16.8 per cent. it was the only cause of death, and in 21.6 per cent. more it played its part either in producing death or in causing the lesion which led to death, i.e., it was the sole or part cause of death in 38.4 per cent. Of the remaining cases, three had phthisis and one presuments

phthisis and one pneumonia.

The influence of granular kidney upon the prognosis of other diseases may be well illustrated by the case of acute pneumonia. In 100 fatal cases which I investigated, 23 showed some pre-existent chronic disease of the lungs or pleura, eight of the heart and ten of the kidneys. Granular kidney is a bilateral, and to a great extent, symmetrical affection, that is to say, both kidneys are affected, though not necessarily to the same extent. The difference between them, however, if there be any, is slight and rarely exceeds an ounce. The kidneys may be much contracted and greatly reduced in size, so that they may not weigh more than 1½ or 2 ozs. each. Extreme contraction such as this is really rare. The kidneys are, it is true, usually reduced in size and weight, but by no means to the extent that seems generally believed, while in some instances so far from being smaller than normal they may be much above the average size and weight. In other words, there are large as well as small granular kidneys, just as there are large and small cirrhotic livers. The kidneys, moreover, are

⁽a) Abstract of lecture delivered at the Medical Society of London on Monday, February 6th, 1899.

not always granular on the surface, though microscopically the interstitial change may be marked enough.

The typical granular kidney is small, contracted, hard, cirrhotic or granular, has a nodular surface, often studded with numerous cysts. On section the whole kidney is found to be cirrhotic and wasted, but the wasting affects chiefly the cortical region. The changes consist in fibroid induration and cellular degeneration. Though granular kidney is described as chronic interstitial nephritis, it is an open question how far these changes are in reality of inflammatory origin. Certainly in most cases we have no more evidence of inflammatory processes in the cirrhotic kidney than we have in the cirrhotic liver.

Granular kidneys are sometimes described as of two kinds, the white and the red, and the difference in colour is held by many to denote difference in origin, and they are accordingly called the contracted white and the contracted red. The small white is stated to be generally somewhat larger than the red, to be less granular on the surface, and to have more cells left, these cells being in a condition of fatty change, to which the colour is referred. These statements are not, in my experience, correct; for small white kidneys are often quite as small and as granular on the surface as the small red, and may have quite as few, or even fewer, cells left, and these cells are often not fatty. The two forms certainly exist.

The term "contracted white" introduces confusion, and seems to assume what ought to be proved, viz., the different origin of the two forms. It suggests that the small white is but the later stage of the large white kidney. It assumes that every stage can bed monstrated between the large white kidney of chronic parenchymatous nephritis, through the contracting white to the contracted white. If this was the usual sequence of events, it ought to be capable of easy clinical proof. Pathologicall, it is easy to show that chronic parenchymatous, or the large white kidney, presents interstitial changes of a contracting kind, but the weak link in the chain is between the so-called contracting form and the contracted form.

If the distinction between the two forms is to be made, it would be very much better to speak of them as small white and small red, or as white cirrhotic and red cirrhotic, rather than white and red contracted kidneys. For myself I consider the difference is really one of colour chiefly. Microscopically I do not see that any clear distinction can be drawn.

If, pathologically, the distinction between the two forms is open to question, clinically, so far as I can see, no distinction at all can be drawn between them; that is to say, with exactly the same clinical symptoms we may find the kidneys in the one case white, and in the other case red. Granular kidney is often described as chronic interstitial nephritis, but all forms of chronic interstitial nephritis are not necessarily granular kidney.

First of all must be cut out of the category of granular kidney all those cases in which the lesion is unilateral; for example, that which results from obstruction to the ureters.

Again, all cases of fatty patchy fibrosis, e.g., the results infarcts or gummata, even if both kidneys are involved, must be excluded, for they do not produce the clinical symptoms of granular kidney.

Even when the lesions are bilateral and both kidneys are affected, I should still exclude from the category of granular kidney certain forms of chronic interstitial nephritis which are often included pathologically, though clinically they are distinct. I refer to the degenerate kidneys met with in connection with advanced atheromatous disease or with the chronic gout of elderly persons, in fact, the kidneys, which are commonly called senile or gouty.

These kidneys are often markedly interstitial, and

These kidneys are often markedly interstitial, and there is a good deal of fatty and cellular degeneration, giving the surface a mottled appearance, but they need not necessarily be granular, and are usually large. Moreover, the cases need not run the clinical course of granular kidney.

Eliminating these various forms, we are left with a pathological group of cases of interstitial nephritis

kidneys of a definite character, which we commonly recognise by the term granular or cirrhotic kidneys.

In most recent writings, granular kidney is divided into two forms, the arterio-sclerotic and the renal, and these are often dealt with in different places, the one form under diseases of the vessels, and the other under diseases of the kidney, so that in order to gain a complete view of granular kidney as a disease, it has to be read in different chapters. This is very inconvenient and confusing, and suggests a marked difference between the two forms which, clinically, does not exist. It has, however, one advantage in that it fixes attention upon the question which is still at issue, viz., whether it is in the vessels or in the kidney itself that the primary causes of the disease are to be sought.

Acute nephritis attacks the cells primarily and chiefly, but the interstitial tissues are always involved to some extent, and the more so the longer the disease has existed. This small-celled infiltration may in time end in the production of connective tissue at first in part only, in other cases more widely distributed, and there will be the more of it the longer the disease has lasted. large, red kidney of acute nephritis passes, as the disease lasts, gradually into the large white. In the large white kidney some interstitial charge is often found, sometimes local, at other times more diffuse; and admitting that pathological connective tissue contracts in the kidney as elsewhere, we should expect the large white kidney in time to become smaller, to undergo a certain degree of contraction in parts if not as a whole, and of this we have frequent pathological proof. The kidney is then described as contracting white. It is even conceivable theoretically that the contraction might go much further, so that in time we night have the large white kidney passing into what may be described as a small white kidney, or even possibly ending in a small red kidney.

Now, admitting the pathological possibility that acute parenchymatous nephritis might end in a granular kidney, if this actually occurred frequently it ought to be capable of easy clinical proof; for the symptoms of acute nephritis are not such as are likely to be often overlooked by the patient or by the friends. Such cases are recorded, but they are certainly rare, and many of them prove on careful critical investigation not to be so conclusive as they at first sight appear. I have been on the watch for them for years, and although I have seen many in which the lesion has gone so far as to produce a somewhat diminished white kidney, the majority of such kidneys are still much above normal size. I have never traced a single case beyond this, i.e., as far as a small white kidney. I do not say that it does not occur; on the contrary, I believe it may. I merely say that so far I have failed to observe it. It might be urged that marked contraction in granular kidney would be more frequent if the patients lived long enough. But it does not necessarily follow, even when the symptoms of chronic parenchymatous nephritis have lasted for many years that a contracted kidney will result. I know of a woman who has had several attacks of parenchymatous nephritis in the course of thirteen years, and who has never at any time lost the albumen from the urine; yet now, at the end of thirteen years, her arteries are thin and her heart not hypertrophied, she appears in fair health, and her retine are normal. There are, in fact, in spite of the long duration of the case, no clinical signs whatever which would justify the diagnosis of granular kidney.

Nor can any closer relation be proved by the clinical history to exist between granular kidney and antecedent acute nephritis. It is quite unusual in cases of granular kidney to obtain any history of symptoms which would in any way justify the diagnosis of acute nephritis. This fact has been always insisted on as long as granular kidney is recognised as a disease, and is generally accepted.

Even when the history of antecedent acute nephritis is obtained it does not necessarily follow that the granular kidney has been the result of it.

The occurrence of acute nephritis is no proof in itself that prior to the acute nephritis the kidney was sound, or in other words, that if after an attack of acute nephritis the kidneys are found granular they became granular as the result of the acute attack.

For, on the one hand, it is not uncommon in the course of a case already recognised as one of granular kidney to see acute parenchymatous nephritis develop; and, on the other, to see a patient hitherto believed to be healthy with the symptoms of acute parenchymatous nephritis, and yet for that patient to present thickened arteries, and even eye changes, which show that the disease really dated long before the commencement of the so-called acute attack; in other words, that the patient has got acute nephritis in both cases alike because the kidneys were already diseased. Indeed, I think we may almost go so far as to say that as in children acute parenchymatous nephritis raises a strong presumption in favour of a recent attack of scarlet fever, so in the adult it ought to suggest the suspicions that the kidneys were previously unsound, in other words, granular. Of this I am quite sure, that if in cases of acute nephritis in the adult the signs of granular kidney be looked for they will very frequently be found. If then, in spite of the fact in the majority of cases of granular kidney, the history and symptoms of nephritis are lacking, granular kidney is still to be referred to some antecedent nephritis, it follows that the initial attack must either have been slight, and therefore overlooked, or else that it was of some peculiar and specially latent kind.

It is evident from what has been said that it is only in a very small number of cases that a history of antecedent acute nephritis can be obtained; that in still fewer instances can a case be traced from an initial acute nephritis to granular kidney. It follows, therefore, that most cases of granular kidney must be referred to some other origin.

The changes in the arteries with granular kidney are general, widespread in fact, universal throughout the whole body. They are found in all parts alike, in the kidney for instance, as well as the brain, eye, spinal cord, or even skin.

Now, there are only two forms in general arterial change recognised in pathology; viz., atheroma, and that -connected with granular kidney

Atheroma is a well-marked disease of the vessels. It is the degeneration which is usual as age advances, and though sometimes met with in earlier life, and even cometimes in quite young people, it is certainly a comparatively rare affection at the time when the changes of granular kidney are most common.

Atheroma being a general disease will, of course, affect the renal arteries like any other, and will produce in the kidneys similar changes to those to which it leads in

other cellular organs, e.g., in the brain.

Thus it is not at all uncommon in the later periods of life to find the kidneys large and mottled, showing a good deal of interstitial tissue and of cellular change; yet the atheromatous or senile changes do not as a rule, though they may sometimes, lead to the well-known granular contracted kidney. Of course old persons may suffer from granular kidney, and the two conditions may be associated. But, for all that, if the question be regarded without bias and in a general, comprehensive way, it must be acknowledged that atheromatous diseases of the arteries, and the changes of granular kidney, are different in kind as well as in history. In granular kidney the thickening of the vessels is fairly uniform. At any rate, it does not occur in the irregular patches if atheroma is universal.

As to the exact nature of the change in the vessels, opinions still differ, as they have done from the first There can be no doubt that there is a considerable amount of muscular hypertrophy in the vessels, or that it is associated in many cases with changes in the intima as well as in the adventitia, which are not atheromatous, and yet are of a marked character.

The relation between the cardio-vascular and the renal lesions is very difficult to determine. So far as the cardio-vascular symptoms go, I think we may say this. that the cardiac lesions being of the nature of hypertrophy, must, as in other cases, be the response of the heart to some extra work thrown upon it of a permanent kind; it must therefore be secondary. It certainly seems more probable that both the heart and the vessels

hypertrophy together, for the purpose of assisting the circulation to overcome some obstruction. If this be so the obstruction must be peripherally seated, and must be sought therefore in the small peripheral arteries or capillaries.

In these peripheral vessels, the possible causes of obstruction are two: either there must be a structural change, that is to say, an anatomical lesion, or some functional disturbance, which interferes with the passage

of the circulation through the vessels. If the change be structural and the lesions of the peripheral vessels are of a degenerative character, being general throughout the whole of the body they would involve the kidneys as well as other parts, and in this way it is conceivable that the kidney disease might ba co-ordinate or subordinate part of the general vascular disease. This is a theory which is now indicated by the term arterial-sclerosis, and such kidneys are described as arterio-sclerotic kidneys.

If, on the other hand, the change here be not of a structural kind, but a functional one, any structural change that is found being of a secondary and subsequent order, the obstruction must depend upon some impurity in the blood. But this impurity of the blood, which renders it more or less obnoxious to the tissues, may be either of a renal or extra-renal origin. If of extra-renal origin then the result may be the same as in the former case, viz., a general vascular disease which affects the kidney as well But it may also be of a renal origin, in as other parts which case there must have been some renal mischief antecedent. Thus even from the point of view of the vessels we are brought back again to the two original views about which so much discussion has raged, viz., whether the disease is primarily arterial or primarily renal.

If the changes in the vessels be regarded as primary, as they certainly are in atheroma and may be also in granular kidney, then it might be possible to find cases of marked changes in the vessels with little or no changes in the kidney. And the same would be true if the changes in the vessels and in the kidnev both stood in relation to common cause. It is only by studying the beginnings of the disease, that is to say granular kidney in its early stages, that we can hope to arrive at a solution of these difficulties; for in the later stages all these changes are present together, and it is difficult, if not impossible, to form any opinion as to precedence of the one or the

From whatever point of view, then. we regard granular kidney, whether pathological or clinical, we come to the same conclusion, viz., that whether primarily arterial or primarily renal, granular kidney is a disease sui generis and ought on that account to be treated, in writing on the subject, under a separate heading, and not split up, as it generally is, between diseases of the arteries on the one hand and diseases of the kidney on the other.

Granular kidney is a very insidious disease. For a long time it presents no symptoms at all, and can be recog-nised then by physical signs alone. The only definite symptom, perhaps, in the early stage (and even this is not constant), is an increased frequency of micturition. especially at night; but as this has been of such gradual ons t that the patient has become quite accustomed to it, and does not regard it as peculiar, no complaint is made of it unless it be extreme, and the history of it is often only to be elicited on pointed questioning. When symptoms arise the disease is already far advanced. oth-r words, the symptoms do n t occur until late in the disease.

The symptoms fall like the lesions, into two groups, viz., cardio-vascular and renal. Speaking generally, the cardio-vascular are earlier than the renal. The cardiac symptoms are those of heart-failure, more or less pronounced. The vascular symptoms are the more or less mechanical effects of the vascular lesion, and consist chiefly of hemorrhage and its results. The renal symptoms are the latest to develop and fall into two The renal groups according as they are of gradual development or of sudden onset, and they are frequently described as chronic and acute uramia respectively.

I should prefer to call them acute and chronic renal

toxemia. Both alike are to be connected with the wasting in the kidneys and its consequent defective action. The gradual and progressive wasting is attended with the gradual and progressive development of the chronic form of uremia.

Renal cachexia is the name that I should prefer to give to chronic uræmia. It strongly resembles, both in character and course, the cachexia that is seen in a variety of other diseases, e.g., in Addison's disease, in the later stages of cirrhosis hepatis, in diabetes, and malignant disease. It consists in a gradually increasing anæmia and asthenia, associated with various miscellaneous symptoms. The symptoms are similar in kind, and differ from them only in the rate of development, to those that are seen after complete obstruction of the ureters or removal of the kidneys, which has been experimentally produced in animals or observed in man as the result of pathological causes or surgical operation.

The symptoms in all these cases are similar, but differ from those which are usually described as acute uræmia, and the difference is probably not one of degree only but of kind, so that I think they ought to be distinguished by different names; for the first I should reserve the term renal cachexia, for the second I should use that term which is generally accepted, viz., uræmia, and both alike, both the cachexia and the uræmia, may be of slow or sudden development.

I propose to deal with the signs and symptoms of the disease in this order.

(1) The physical signs; (2) the cardio-vascular symptoms; (3) the renal symptoms. It is the early signs of the disease rather than the late symptoms that are of importance. What is required is an early diagnosis before the disease is far advanced, and this is essential if light is to be thrown upon the causes and course of the disease, or if influence upon it is to be successfully exerted by treatment. In the early stage the diagnosis is to be made by physical signs and not by symptoms. The physical signs are high tension and thickened arteries, hypertrophy of the heart and albuminuria. When these are all present together the diagnosis is easy, even in the young, and the diagnosis thus made during life is verified post-mortem. But if one or other of these physical signs is absent the question arises, of what value are those remaining? For instance, if albumin is absent, what do high tension and thickened arteries mean, in the young? Or if the arteries are not thick or the tension high, but albumin be present, what is the significance of the albuminuria?

Each of these questions is of great clinical importance. We know that the vascular changes, viz., thickened arteries and high pulse-tension develop so early in the course of granular kidney that they seem to be rather coincident or, as some maintain, even antecedent, phenomena than effects consequent upon and produced by the kidney lesion. If this were so, vascular changes might be found without the kidney lesion, and such cases are described. Post-mortem evidence would point to hypertrophy of the heart as a most important sign of granular kidney, and so it is in the later stages, where the cardiac enlargement is such as to be easily made out by percussion. In the early stages it is of very little assistance because of the difficulty in diagnosing it then.

The hypertrophy of the heart is probably secondary to the vascular changes and the result of them, and therefore not of the prime importance they are or so likely to be met with early.

Thickening of the arteries is one of the cardinal signs of the disease, and is never absent in advanced cases. I have already referred to the fact that thickening of the arteries is by no means uncommon in young people, and the question as to what its significance is becomes important in relation to the early signs of granular kidney. At this stage the thickening cannot often be of an atheromatous nature, for although atheroma does occur in early life it is very much rarer than the thickening I am speaking of. The change is in great part muscular, no doubt, as it is in granular kidney, and the effect of nitrate of amyl upon it is the same. Arterial thickening always rouses my suspicion in young people, and leads me to make a careful examination for other

symptoms; sometimes they are found, and the diagnosis is clear; but not unfrequently nothing else is found, and the doubt remains as to the meaning of this thickening in relation to granular kidney, but that it is pathological there can be no question.

In well marked (i.e., advanced) granular kidney the high-tension pulse, as well as the thickened arteries, are well recognised. The tension is measured between the pulse waves; the arteries therefore feel abnormally full as well as abnormally tense. When the heart begins to fail, the diminished force does not necessarily alter the character wave. When the tension falls, the fall is due to a failure of the artery and not necessarily of the heart at all, though both may fail together. The low tension then observed is a neuro-paralytic phenomenon and a bad sign. It occurs only in the later stages of the disease, but may then continue for some time. Though the tension be low, the thickening of the arteries can still be easily made out and is as characteristic as ever.

A persistently high tension, to whatever cause due, is of itself pernicious, but not so with granular kidney, paradoxical as this may seem. The patient is best without granular kidneys, but if the kidneys be granular it is better that the tension should be high rather than low; in other words, the patient is worse with a low tension, and this explains the benefit of digitalis in such cases; it does so much good by raising the arterial tension.

This low arterial tension, or rather the fall in tension, in the later stages of granular kidney is of great clinical importance, the value of which Sir William Broadbent has lately emphasised.

I may refer to one other phenomenon which, though implied by what has just been said, is not generally recognised, although easy to be observed if looked for. I refer to the irregular fluctations in tension which take place in the later stages of the disease, before the tension becomes persistently low. Thus, it may be felt to vary considerably, even in very short spaces of time; for instance, while the finger is placed upon the pulse. In the early stages of granular kidney, go back as far as we may, as soon as the disease is diagnosable, the pulse tension is high and the artery thickened. The question arises, what is the value of a high pulse tension in a person in whom there is not yet other evidence enough to diagnose granular kidney by? Temporary or transient increase of tension may occur in a variety of affections, but it is not to these that I refer. I am dealing with those cases in which the tension is persistently raised.

cases in which the tension is pers stently raised.

Sir William Broadbent, differing as he does from Mahomed in theory, yet attaches quite as great significance to this increase of pulse tension. He describes as the ultimate results of this increased tension a variety of symptoms, cardiac failure, general disturbances of health, a sort of cachexia, and even hæmorrhage, which, as he stated, could be truly predicted long before it occurred. There are, of course, the same symptoms as those produced by advanced granular kidney. If the kidneys are not granular in these cases, of which no proof is given, the arteries must, at any rate, become diseased if hæmorrhage is to occur; for I can suppose it will hardly be asserted that mere increase of tension can lead to the rupture of healthy vessels. In respect of the results, therefore, Sir Wm. Broadbent's views and Mahomed's views agree exactly, the difference culy is that whereas Mahomed referred the results to granular kidney, Sir Wm. Broadbent seems not to do so. I cannot help adopting the views that Mahomed urged.

These differences in theory would remain a matter of opinion still, if there were not some fresh facts by which to elucidate them, and these have been obtained by the more exact and careful study of the early eye changes met with in granular kidnev.. As I shall show shortly, our knowledge of the early stages of albuminuric retinitis has been greatly extended of recent years. If, in mary of these doubtful cases of high pulse tension, and thickened artery albuminuric retinitis or the early changes which lead to it are found, even in the cases in which albumin may not be present in the urine, the diagnosis of granular kidney will be surely justified. Considering that albuminuric retinitis is not of course invariably found even in advanced granular kidney, that

it can be discovered in these earlier doubtful cases is a significant fact, which throws a startling light upon many of those other cases which must still remain more or less doubtful. Some of these doubtful cases, therefore, at any rate, must be referred to the group of granular kidner, and the possibility that a much larger number of them can be fairly so referred is therefore increased. It appears to me, therefore, that the presumption is very strong indeed in favour of these cases of high pulse tension as well as those of thickened arteries in the young being the initial stages of granular kidney which it is so important to recognise.

Clinical Records.

MONKSTOWN HOSPITAL.

Trephining for Cerebral Abscess.

Under the care of Mr. Hy. GRAY CROLY, F.R.C.S.

On Saturday last, February 11th, Mr Henry Croly, trephined over the right temporo sphenoidal lobe in a young woman, set. 24, who had for some time past suffered from chronic otitis media. After admission to hospital she developed serious brain symptoms and temperature. A consultation was held between Dr. Hawtrey Benson, consulting physician, and Dr. Beatty, physician to the hospital. Mr. H. Gray Croly, consulting surgeon, and Mr. H. Croly attended. It was decided to operate, and a portion of bone was accordingly removed, pus escaped with flakes.

The patient bore the operation well, and got immediate lief. We hope to publish a full report of this interrelief. esting and important case later on.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON. MEETING HELD FRIDAY, FEBRUARY 10TH, 1899.

The President, Mr. LANGTON, F.RC.S., in the Chair.

TUBERCULOUS CAVITIES IN THE LUNGS GIVING RISE TO GASEOUS METASTATIC ABSCESSES.

Mr. W. G. Spencer described an exceptional case in which abscesses formed in the back, in the right pleura, and in the upper part of the left thigh, the latter bursting into the rectum through the great sciatic notch. Meanwhile the disease of the lungs gave rise to practically neither symptoms nor signs. The patient was a West African negro, set. 22, who was attended by Dr. Denue for pain in the left knee, frequent headaches and vomiting, which he had had for eight months. A large superficial abscess extending from the left scapula to the lowest rib was opened, but no communication with the chest found. As the patient still had fever he was admitted to the Westminster Hospital, where a tympanitic swelling was found occupying the upper portion of the left thigh and buttock. On opening this multiloculated abscess, gas and pus with a fæcal odour escaped, and it was found to communicate with the rectum through the great sciatic notch. There was no ulceration of the rectum nor infiltration of the ischio-rectal fossæ. Later on the patient suddenly developed an acute effusion into the right pleura. The fluid aspirated having a fæcal odour and containing pus cells, the right pleura was consequently drained. Then followed a period in which the patient declared himself better, the abscesses in the back and the pleura wound nearly closed, the man insisted upon getting up and asked repeatedly to be discharged. The septic fever, however, continued, and foul yellow pus was discharged from the thigh in spite of frequent irrigation. All the evidence of chest disease was an occasional cough and a few rales. Yet malaria, dysentery, typhoid fever, and secal fistula from intestinal ulceration, appeared to be clearly negatived. One day, after being five months under observation, the patient suddenly collapsed and died in Post-mortem showed a tuberculous cavity four hours.

in the upper part of the right lung, the size of an orange, filled with a gummy purulent fluid, whilst the rest of the right and the left lung contained numerous caseous tubercles; extensive tuberculous caries of the sixth. seventh, and eighth ribs on the left side, and of the eighth and ninth ribs on the right side; the right pleura thickened and adherent; the upper part of the left thigh and buttock completely occupied by multilocular abscess cavities. There was no tuberculous ulceration of the intestines.

DR KINGSTON FOWLER asked whether tubercle bacilli had been found in the lungs. He was not aware of any cases in which gas and foetid effusion had occurred in the pleura apart from gangrene or perforation of the lung.

Mr. Makins said it was probably a mixed infection, and suggested that possibly the feetid abscesses were not directly traceable to the pulmonary lesions.

Dr. J. H. BRYANT asked if any anaërobic cultures had been made, and recalled the fact that the bacillus aerogenes capsulatus had been demonstrated in connection with gaseous abscess of the liver and in a case of pneumothorax without perforation. He himself had ound the bacillus coli communis in such a case, and he handed round photographs of the liver from that case.

Mr. Spencer, in reply, said the bacillus coli was found in the pus of the abscesses. Tubercle bacilli had been found in the lungs after death. The abscess in the back might have spread from the lung by way of the rib, but the abscess in the thigh must have been metastatic.

Dr. Thomas Barlow and Dr. F. E. Batten read a paper on a case of

MYOPATHY WITH AUTOPSY IN A BOY, AGED FIVE YEARS.

The case was shown at the Clinical Society in November, 1894, and the following account of the case was given: -The boy had suffered from weakness of the back and legs since birth, he has never talked clear'y, but is considered fairly intelligent, he has never had any severe illness. He was a healthy baby, and nothing was noted to be amiss till the time when he should have begun to walk. No similar affection occurred in any member of the family, except possibly his sister (seen by one of us, T. B.), in whom it is noted that the pectorals and del-toids were small. Cn admission to the hospital the following note was taken :- He is an intelligent-looking boy, his face, eyes, mouth, and tongue present nothing abnormal. His speech is of the type known as "idio-glossia." He sits up in bed and holds the back very straight, if placed on his back he is unable to raise himself into the sitting position without turning on to his face. The child is unable to stand, and the legs are flexed at the hip and knee. The muscles are everywhere very weak and thin and have a tough feeling. In the upper limbs all movements seem capable of being performed. The latissimus dorsi and pectoral muscles are very wasted, the infraspinatus is comparatively good. In the lower limb both limbs are equally wasted, no hypertrophy, all movements capable of being performed but the legs cannot be fully extended. The knee-jerks are present, equal and active. Sensation is normal to all forms of stimulation, and the electrical examination show only a diminution to both faradic and galvanic elements. The boy developed an attack of gastro-enteritis and died. At the autopsy was found some defect in the arches of the lower lumbar vertebræ, the spinal cord and brain appeared normal. The pectoral muscles were very poorly developed, the serratus was small, the biceps was fairly developed but was pale, the rectus abdeminis muscle appeared normal. The glu ei were converted into masses of fat, and the rectus femoris was poor and thin. Microscopically no lesion could be found in the brain, medulla, and spinal cord. The anterior horn cells appeared quite normal except for the deposit of some pigment which does not usually occur in young subjects. The medullated sheath of the root fibres appeared thinned out and not possessed of the regular contour of the normal fibres. In the muscles the following changes were found Extreme variation in the size of the muscle fibres, some being considerably larger than normal, increase in the interstitial tissue between the Vacuolation in some fibres and a very considerfibres.

able deposit of fat between the fibres, a fine granular (? fatty) change was found within certain muscle fibres. rendered apparent by staining in Marchi's fluid. The muscle spindles form a striking feature in sections of the muscles and are apparently normal. The sensory nature of these organs is no longer doubted, and it is argued that if it can be proved that these organs remain normal while the rest of the muscles undergoes atrophy, then it is probable that the primary lesion in this disease lies in that part of the nervous system where the motor and sensory paths lie separate. The authors assign the case to the group known as the Leyden-Mobius, although hereditary history was wanting in the present case. The muscular atrophy corresponds to the late pseudo-hyper-

Dr. Bablow called attention to certain clinical features which were at the time as puzzling as they were remarkable. When the case was shown before the Society he took the view that it was of a type intermediate between the cases of myopathy described by Erb and the pseudo-hypertrophic paralysis described by Duchenne, approximating rather to the latter. Even the most atrophied muscles still presented the very note-worthy toughening and fibroid-feel, especially marked in the muscles of the lower limb. None of the muscles of the upper limb presented the absolute atrophy met with in the more advanced cases of Erb's type. He admitted that the absence of the hereditary element in this case was remarkable, but suggested that possibly, if they could keep the other members of the family under observation, this might develop later on. He thought the pathological appearances supported the view as to the nature of these cases, viz., that they were developmental, and that though there might not be a definite congenital defect at birth, there was a pronounced ten-dency to degeneration which came out at an early period. The noteworthy fact that the laminæ of the lower vertebræ were wanting lent support to the supposition that there the case must be classed with those in which there was a potential congenital defect. He remarked on the slight tenacity of life which these subjects exhibited, as illustrated by the rapidity with which this patient succumbed to an inexplicable attack of gastro-enteritis.

Dr. Beevor thought too much stress was generally laid on the matter of hypertrophy, for before Duchenne had described his cases of pseudo-hypertrophic paralysis, cases had been recorded in which there was no hypertrophy. The microscopical examination showed that some of the muscular fibres were definitely hypertrophied. This actual hypertrophy had, in some cases, been the cause of the visible hypertrophy, but in this particular case there was no visible hypertrophy, so that this actual hypertrophy might exist without any outward and visible

increase in size.

Dr. Abrahams thought the case certainly supported the view held by Erb that all these myopathes had a c mmon origin. With regard to the hypertrophy of the individual fibres one was struck with the great similarity between these specimeus and those of disseminated sclerosis in the nerve fibres. There one saw some fibres hypertrophied and others wasted, and in both cases the hypertrophy was of the degenerative kind. He recalled that in 1894 Babes had described certain changes in the motor ends of nerves in cases of pseudo-hypertrophic paralysis, something like these of peripheral neuritis which were figured in his atlas. These had not been generally accepted, and he asked the authors whether they were in a position to confirm these changes.

Dr. SAVILL said the question was after all whether it was not really a nerve change, and asked whether any changes in the nerves were seen. Two things had struck him in studying these cases, first the small differences there were between the different kinds of myopathies described by various observers. As a matter of fact he thought Duchenne why Erb's type and Leyden's type were regarded as different or why Duchenne's pseudo-hypertrophic paralysis should be regarded as different from primitive myopathy. He thought they were really the same. In the first place cases with hypertrophy and others with atrophy had been observed in members of the same tarming. He agreed with Dr. Barlow that it was de-

cidedly an hereditary disease. Secondly, the electrical changes had not been sufficiently studied. It had been said that there were no electrical changes in primitive myopathy, but in this case there was a decided diminution to Faradism and a modified form of reaction of degeneration to galvanism. His own idea was that it was the lower motor neuron that was affected, and that it was primarily a nerve disease. If the same changes were observed in the myeline sheath or other part of the nerve that would go far to elucidate the pathology of these interesting if rare cases.

Dr. BATTEN, in reply, said he had not examined the motor ends in the muscles, pathologically, nor did he know how to proceed to do so. With regard to the changes in the nerves he thought they had taken place in the medullary sheath in the nerve root fibres and not in

the nerves in the muscles.

RESULTS OF OPERATIONS FOR ENLARGED PROSTATE.

Mr John R. Lunn read a paper on this subject, which

will be found on page 156.

The President recalled a case of his own before the introduction of this operation. The patient was a man. æt. 68, with tuberculous disease of the right testicle and a considerably enlarged prostate, which made his life a misery, as he had to get up twenty times a night to pass water. He removed the testicle and then lost sight of the patient for three or four years When he next saw him he had a similar condition of the left testicle, but he noticed then that the corresponding right half of the prostate had undergone marked diminution. He removed the other testicle, and a further diminution of the size of the prostate as a whole ensued, and the patient was still alive at the age of 87, and was only obliged to get up twice or three times during the night. He referred to the mental disturbances which sometimes followed castration and asked if the author had observed anything of the kind in his cases. He himself had met with this acute senility two or three times. He objected to the use of the term surgical kidneys, they being rather asur gical kidneys.

Mr. W. G. SPENCER observed that some of the patients had died of surgical kidney due to the resistance of an enlarged prostate which the operation had not averted. This reminded them of the fact that the operation did not enable them to dispense with the necessity of adopting the usual treatment such as washing out the bladder. drainage, &c. He agreed that the senile degeneration that followed was sometimes of an acute character, and in other cases there had been described an eunuchoid condition, and these facts made one rather reluctant to

advise the operation.

HARVEIAN SOCIETY OF LONDON. CLINICAL MEETING HELD ON FEBRUARY 2ND, 1899.

The President, Mr. HENRY JULER, F.R.C.S., in the Chair.

Mr. Raymond Johnson showed a girl, æt. 8, who was the subject of a large congenital cystic hygroma of the neck. She had been under observation since the age of sixteen months, and the tumour had progressively but slowly diminished in size. On three occasions the tumour had been the seat of attacks of violent acute inflammation, during which the swelling became enormously increased in size, and there was rather severe constitutional disturbance. On each occasion the inflammation had subsided spontaneously, and was followed by a more rapid shrinking of the tumour. One of the largest cysts had been treated by drainage, but, in view of the very marked tendency of tumour to shrink, and its extent and diffuse character, it was not proposed to make any attempt to remove it by operation.

Mr D'ARCY Power remarked that such growths, in the neck, usually involved the lobule of the ear, as had evidently been the case in this child, though the lobule of

the bulk of the growth in three of the cases, but in the fourth it was so extensive, and involved such important attractures, that much had to be left behind. Yet, in structures, that much had to be left behind. Yet, in this case, the remainder of the growth absolutely vanished in the course of a few months, and after attacks of lymphangitis like those described by Mr. Johnson.

In reply to Mr. E. L. Hunt, Mr. Johnson said that the tumour in his case could be distinguished from a deeplyseated dermoid chiefly by its diffuse character and the

fact that it was multilocular.

Mr. JACKSON CLARKE showed a little girl, at. 3, who had several congenital deformities. The deformities of the hands and feet had been cured by gradual methods, and he expressed his preference for such methods over procedures such as Phelp's operation which, in his opinion was undesirable as applied to club foot in children.

Mr. D'ARCY Power asked Mr. Jackson Clarke whether he had been able to elicit any history of syphilis in this case, or whether there was any evidence of placental inflammation. He thought that the dimpling had been caused by the presence of allantoic bands for it was so exactly symmetrical. The imitation of these bands had led to the slight hypertrophy of the bone underlying each dimple.

Mr. CLARKE replied in the negative.

A CASE OF MUMPS, WITH MARKED ENLARGEM NT OF THE SPLEEN.

The patient, exhibited by Dr. EWART, a healthy boy, æt. 13, was admitted into hospital on the third day of the attack, with the characteristic swelling of the left parotid. The affection remained limited to the left side, and ran a mild course without pyrexia. The only com-plication was an enlargement of the spleen, which per-sisted for several days, and gradually subsided as the parotid gland returned to its normal size. Tracings of the splenic dulness taken during the period of enlargement and after recovery were shown. Dr. Ewart had not found in text-books any reference to this complication, which may perhaps sometimes occur unnoticed. In this case it gave rise to no symptoms. The dulness measured 61 inches in the horizontal and 5 inches in the vertical direction. The enlargement took place upwards, the spleen projecting half an inch only below the costal arch. The spleen when percussed at the meeting was of normal size, and yielded the "boxy" percussion note which, as recently pointed out, sometimes replices the splenic dulness. A specimen of the blood had been stained for micro-organisms by Mr. Hunt with negative results.

Dr. Maguire remarked that this was a case in which his method of palpation was particularly valuable for defining the outline of the spleen and avoided the errors which beset the employment of percussion in such cases.

At the invitation of the President,

Dr. WILLIAM HILL showed a young woman who had been the subject of chronic suppuration in the middle ear, and who for two years had suffered from facial paralysis, associated with paralysis of the corresponding half of the soft palate. No evidence of diphtheria was obtainable. The interest of the case consisted chiefly in its bearing upon the question as to whether or not the muscles of the palate received any part of their nervous

supply from the facial nerve.

Dr. HERBERT TILLEY said the occurrence, if real, of combined facial and unilateral palatal paralysis, pointed to the palate having a double nerve supply—the facial through the vidian, and the spinal accessory by the pharyngeal branches of the vagus, the latter being the most constant, and probably the sole one. He referred to three cases of the kind which had recently come under his notice: - (1) A man, æt. 55, who complained of "constant accumulation of phlegm in the throat," and on examination showed paralysis of soft palate (left side), left side of pharynx, left vocal cord, left sterno-mastoid, and upper part of left trapezius. (2) Case of syringo-myelia in girl, ett. 15, with paralysis of right palate, right side of pharynx, right vocal cord, together with other lesions characteristic of the disease. (3) A case

and on recovering from it was "paralysed in the left arm and leg" for three weeks, and also "in the throat." Examination of the lat er shows paralysis of the left side of the palate, pharynx, and left vocal cord, but not of the sterno-mastoid or trapezius. Such cases proved indisputably that the spinal accessory supplies the palate and pharynx and larynx (motor fibres), and bore out the experimental evidence.

Dr. Guthrie only accepted the diagnosis of paralysis of the palate on the strength of the reaction of degenera-

Diphtheritic Tracheitis with Temporary Obstruction of the Right Bronchus in the Adult.—Dr. EWART and Mr. E. L. Hunt exhibited a series of tubular casts of the trachea expectorated on the third, fourth, and fifth days of the attack, by a maid servant, æt. 32, who was now recovering, after a pyrexial period of nineteen days, from a severe pulmonary catarrh, due, as shown by repeated cultivation, to diphtheria. She had been injected on the third and the fifth day with 4,000 units of antitoxin. On the third day the laryngoscope had shown the presence of membrane immediately above the glottis, but the vocal cords were free. There was considerable dyspnœea on exertion, but no apparent distress of breathing in recumbency, though the rate of pulse and respiration remained rapid, with some cyanosis of the face and lips throughout the attack. For s veral days there was loss of respiratory sounds and great diminution of respiratory movement over the right side of the chest, which were attributed to impaction of membrane in the right bronchus, as there was no evidence of any inhala-tion of food having occurred. With the return of the respiratory function abundant râles gradually developed. The patient was completely aphonic for fifteen days, but in contrast with the familiar symptoms of membranous croup in children the cough was not 'croupy," and there was no strider or spasm of the glottis. in alarming attack of heart failure had occurred on the tenth day, but neither albuminuria nor paralytic symptoms of any kind had hitherto made their appearance.

In answer to a question by the President, Mr. E. L. HUNT remarked that the antitoxin with which the patient was injected was obtained from the Royal College of Physicians. Two injections were given, of 4,000 units each, into the subcutaneous tissue of the abdomen. The injections were given on the third and fifth days of the disease, and were followed by rashes, erythematous, and transient on the arms and legs on the eleventh and fourteenth days of the disease, and about the same time the patient suffered from swelling and redness of the hands and pain on movement in the wrist and finger joints; there were also pain and tenderness in the muscles

of the legs and thighs.

WEST LONDON MEDICO CHIRURGICAL SOCIETY.

meeting of this Society was held in the Society's Rooms at the West London Hospital, on February 3rd.

Dr. S. D. CLIPPINGDALE, President, in the Chair.

A discussion on the "Treatment of Appendicitis" was introduced by Dr. Seymour Taylor, and Mr. McAdam Eccles, and continued by Dr. Donald Hood, Mr. Keetley, Mr. Bidwell, Dr. Caley, Mr. E. T. A. Boyton,

Dr. George Eccles, Mr. Lunn, and Dr. Dobson.
Dr. Seymour Taylor in opening the discussion remarked: That so long as physicians recognised the appendix as the cause, in perhaps 90 per cent. of cases, of those groups of symptoms which have been called typhlitis and perityphlitis, a long stride forwards has been made. One further step should be made, viz., to recognise that sepsis by micro-organisms or by their products is the chief or only cause of that fear of peritonitis, whether local or general which is the sequel to appendicitis. He would not say that appendicitis itself is not set up by the influence of fruit stones, grit or other foreign bodies, nor would he deny that the condition other lesions characteristic of the disease. (3) A case the speaker had that day seen at Golden Square, in which a woman, set. 38, after suffering for a few days tuberculous deposit therein; but these alone are not sufficent violent pain in the back of the head, had "a fit," cient to complete the clinical picture. So far as treat-

ment is concerned, the physician's advice may be of the utmost weight and importance in two periods, viz., from the preventive period, when by ordering a patient's diet and mode of life he may postpone or even prevent an attack of appendicitis; and, secondly, when a local tumour having formed he may arrest the progress of the disease at a point short of the formation of pus; for suppuration having once occurred all further treatment must then be at the hands of the surgeon. In the first stage the diet should be largely of a liquid character, but consist also of vegetables and some beef extract. Milk should be rigidly excluded, as it tends to with bulky or scybalous stoo's. In constipation, the second favour stage his experience was strongly in treatment by perfect rest, small doses of opium frequently repeated, and the administration of copious enemata of soap water and olive oil. On the other hand, if competent surgeons by early laparotomy and removal of the appendix could show a death rate which was more favourable than the physician's palliative and expectant treatment, then there could be no two opinions that from the first all cases of appendicitis should be handed over to their care. Should the case, however, have passed on to suppuration, surgical help is needed at once. The delay of an hour even may cause the loss of Then comes a time in many cases, which no one a life. can foretell, when the patient who was apparently in no great danger, is suddenly, as it were, precipitated over the abyss and is beyond all surgical skill. The thermometer will not necessarily be a guide to the existence either of pus or of perforation, but it should be used intelligently in combination with a clinical eye on the tongue and pulse. Finally, he would with all respect impress on their surgical friends to so incise the abdomen in all cases of doubtful obstruction as to readily command the appendix. The site of pain and tenderness is by no means a guide to the seat of disease.

In reviewing the surgical treatment of acute inflammation of the vermiform appendix, Mr. McAdam Eccles said that he considered that surgical interference was called for in all cases where there was no suppuration, whether local or remote; in instances where there was general septic peritonitis; and in many instances between attacks, so that the offending organ might be removed. When an abscess in the right iliac fossa had to be dealt with, he thought that two points needed emphasis, one that a very free exit for the pus should be secured, and the other that nothing more than free drainage, as a rule, should be attempted. His belief was that most cases thus treated do well, and have but little tendency to further trouble from the appendix. He laid stress upon his view that it was not advisable to explore the area of suppuration until time had elapsed, so that peritoneal adhesions, shutting off the general peritoneal cavity, might have formed. The pus did not tend usually to pass into the serous cavity, and therefore too early operation was a mistake.

France.

FROM OUR OWN CORRESPONDENT.

Paris, February 12th, 1899. Appendicitis.

M. Reclus, in referring to the treatment of appendicitis at the last meeting of the Academy of Medicine, said that if one was to consider exclusively medical statistics it would seem paradoxical to advise an operation in every case, it should not be forgotten that persons cured medically remained exposed to new attacks of appendicitis; he knew a patient who had been cured of sixteen attacks, and would have died of the seventeenth, which occurred a month afterwards, if an operation had not been quickly performed. It was true that there were cases which could get well without interference, but there was no means of distinguishing them from those

requiring an operation. Consequently he was of the opinion of M. Dieulafoy that an operation was always necessary. But the question, Should it be done in the acute stage, or would it be better to wait until the acute symptoms had subsided (operation à froid)? majority of surgeons preferred to wait, insisting on the difficulty of recognising the appendix in the inflammatory stage and the possibility of wounding the cocum, and of infecting the peritoneum. Those fears he considered as a good deal exaggerated, for an experienced surgeon could always avoid such dangers. In any case it was impossible to predict the course the affection might take, and, while waiting, the patient might be carried off by acute peritonitis. The wisest plan was to operate as early as possible.

M. Dieulafoy said that he was the much more partisan of an early operation, as the acute symptoms of appendicitis, fever, vomiting, abdominal pain, &c., were frequently followed by a brusque arrest, which did not however presage a favourable turn. On the contrary, the deceptive improvement coincided often with the formation of the gravest lesions, gangrene of the appendicitis, septicæmia, or diffuse peritonitis.

M. Walthier gave statistics of 27 operations done by him last year, all of which, except four, were performed after the acute symptoms had subsided, and all got well; while of the remaining four, one died. If he preferred applying the medical treatment first, it was because he considered the ablation of the appendix more important than was generally believed, and that in the acute stage it was not always possible to remove it.

M. Kirmisson said that he operated twenty-five times in 1898, and twelve of the patients died from diffused peritonitis. If they had been operated on earlier some of them would have been saved.

M. Jalaquier was of the opinion that the present discussion demonstrated clearly that it was impossible to lay down a hard and fast rule as to the treatment of peritonitis. It was certain that the principle of operating as soon as the case was properly diagnosed was very seductive, but unfortunately the surgeon was never called quickly enough in private practice to a patient suffering from appendicitis. He was consequently a partisan of abstention in cases where the symptoms remained localised, applying medical treatment only; within the past year he injected subcutaneously artificial serum.

PLEURISY.

Pleurisy constitutes, as everyone knows, a malady difficult to diagnose as regards the abundance, the seat, the distribution of the liquid in the pleural cavity. The case is specially difficult where adhesions exist dividing the cavity into several compartments. Frequently this complication is only discovered after several times practising thoracentesis. Professor Chauffard reports such a case treated by him in the hospital. The patient was 55 years of age and of a sound constitution. At the end of January he was seized with all the symptoms of pleurisy and decided on entering the hospital. Examination showed an increase in volume of the thoracic wall of the left side. Dulness was present over the whole region and the vibrations abolished up to the middle of the scapula; the dyspnœa was considerable. The same day six ounces of fluid were drawn off by the trocar, the instrument being placed in the eighth intercostal space. The following day no improvement had taken place, on the contrary matters seemed to have grown worse. This time the trocar was passed in the sixth space giving exit to a large quantity of liquid (a quart) to the great relief of the patient. A few days afterwards the needle was passed through the third intercostal space, and a small quantity of liquid removed. Finally, after a fourth operation, by which four ounces were withdrawn, the cavity was considered empty, and the man made a slow recovery.

THE ACADEMY OF MEDICINE.

The demolition of the old Mont de Piété in the rue Bonaparte, to make room for the palatial building which is to be constructed on this central site for the Academy of Medicine, has been completed. The building, higher up in the same street actually inhabited by this body, is a mediæval structure of small dimensions and singularly unprepossessing appearance, and it has for years been scandalously unsuited for the purpose. It is estimated that the new buildings will take about two years to put up, and the cost is put at 832,000 francs, that is to say, between £32,000 and £33,000. This sum will be contributed partly by the State and partly from the funds of the Academy, and we are promised that, from an architectural point of view, the new building will be a masterpiece in this city of masterpieces.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 11th, 1899.
DIETETIC TREATMENT.

In the Munch. Med. Wochensch., 30/98, Hr. G. Treupel has an article on the subject with special reference to the form of treatment in certain classes of cases. The advances in the domain during the last twenty years have been considerable, and bid fair to go still further in the near future. The first subject discussed is the treatment of diabetic mellitus. The aim of treatment in this disease is, first, to diminish the formation of sugar within the system, and, secondly, to use up the sugar existing in the body fluids. Both aims are best reached by limiting the quantity of carbohydrates in the food The restriction should be absolute during the first four weeks of treatment. During this period the patient's diet should consist of albumen and fats, and limited quantities of certain vegetables, tea, coffee, and certain drinks free from carbohydrates. After this period is over, starchy foods may be given, but in certain limited quantities, strict regard being paid to the body-weight and the character of the urine. Beer should be avoided.

Subcutaneous feeding is the next point discussed, the author confining himself to a report on the present stage of the question rather than to conjecture as to the future. Fat lends itself more readily to the purpose of suboutaneous feeding. It is not irritating to the tissues, is heat-giving, and it can be readily stored up in the system in large quantities. Sugar has the advantage of being readily sterilised, it can be stored up in the form of glycogen, and it is easily and well used up in the ordinary tissue change. But against anything like a general use of these substances subcutaneously there are many objections, and, most of all, the painful swelling that takes place in the muscular tissue after their administration. Albumen does not lend itself to suboutaneous injection, it is sterilised with difficulty, is often not assimilated, and does not form a reserve materialand in addition to this the albuminous bodies, to some extent, are poisonous when in the blood,

Artificial foods are next touched upon, and regarding these, he opposed the opinion of Klemperer that the natural products were more suitable. In many cases, for example, in blood diseases, with their accompanying emaciation and exhaustion, in the numerous cases of tuberculosis, admitting of recovery, it is not possible to give such a quantity of the natural foods as will answer the purpose. In such cases the artificial foods find their proper place, and of these the albuminous preparations are the most important. It is important not only that excellent preparations are before the profession (somatose, nutrose, eucasein, sanatogen, sanose), but that such can be procured at a not too exorbitant cost, although the ideal in this respect has not yet been reached. He expressed the hope that when the subject of tissue changes and nutrition are better known that good foods will be forthcoming, not only for the sick, but for the people at large, and at a low cost.

At the Society for Innere Medizin (December 12th) Hr. P. Ehrlich gave an address on

THE RELATION BETWEEN THE CONSTITUTION AND ACTION OF MEDICINES.

The dependance of a knowledge of drugs on chemistry becomes the greater the more one recognises that the action of chemical combination on the organism depends on the presence of certain sharply definable "atomencomplexe" in moleculi, for example, the action of curare on the quaternary ammonium group, the anæsthetising action of cocaine on the presence of the benzoyl group the action of the phenacebineoid antipyretics on the formation of paramidophenol in the system, the affinity of nerves for all the ethyl combination.

The results of this research within this region had not hitherto been of very great importance. Chemical constitution alone does not suffice to explain action. The relationships here were more complicated than in the case of the dyes, in the case of which important conclusions could be drawn from the constitution alone. He had determined that the introduction of the sulphoacid groups would convert poisonous bodies into non-poisonous ones (aniline), the nerve staining properties of certain species could be entirely abolished by the introduction of the same groups. By the introduction of such different groups the diffusion of the body within the system was changed.

The peculiar dissemination of each chemical body within the system was a result of election by the organs. There was no foundation for the view that the vessels in various organs showed different degrees of permeability.

Venilamine, for example, caused an isolated necrosis of the kidney papillæ, acetylparaphenylendiamine a peculiar brown colouration of certain muscular parts of the diaphragm which did not depend on the presence of a derivative of hæmoglobin, but probably on an exidising combination of acetylparaphenylendiamine with the mole cule of the muscle albumen. Except the diaphragm, only muscles of the eyes and the external muscles of the lar, nx were occasionally affected.

The election of the tissues could only be attributed in part to the combination of the body introduced with the protoplasm. Of most of the foreign bodies introduced there could be no question of chemical combination within the system, as the carbo-hydrates, ether, chloro-

form, sulphonal. For these bodies the explanation of the attraction was that lecitine had a great power of solution for them and attracted them. In the case of other bodies the explanation was more difficult, for very different bodies such as aniline and salicylic acid were not chemically combined in the protoplasm, as they could be extracted from the system by indifferent solvents.

Witt believed that the dyes were not chemically united in the fibres, but were like dissolving bodies in their solvent material. In this hypothesis he has brought forward a number of facts in confirmation.

Dyes again gave us an idea of what tissue elements took in the material. It had never yet been observed that in cases of vital staining, the living protoplasm had been coloured, but only certain paraplasmatic granules in the cells. In nerve staining, also, it must not be assumed that the nerve substance itself was coloured, but certain paraplasmatic bodies present in the nerves took on the colour. These facts made it probable that poisons also, such as the alkaloids, were not taken up directly into the protoplasm, but into paraplasmatic elements.

From these considerations the following conclusions could be drawn. In the synthetic preparation of a chemical material from which a definite physiological action is desired, two conditions have to be fulfilled. First, the configuration of the molecule must be such that it could enter into rigid ("starre") solution with the tissue elements in question. Secondly, the molecule must contain an atomcomplex, which exercises a specific action on the protoplasm. Thus, in cocaine, for example, the bearer of the anæsthetising properties is always the benzoyl remnant, whilst the whole remaining molecule is fitted by its configuration to enter into "rigid" solution with the protoplasm, and in this way carries the benzoyl groups into the protoplasm.

Austria.

FROM OUR OWN CORRESPONDENT.]

VIENNA, February 11th, 1899. EDITORIAL CHANGES.

It is interesting to note how easily a medical journal in Vienna changes hands. Without any preliminary announcement or apparent difficulty the new editor of the Wiener Klinische Rundschau briefly states in a few words that "we-Drs. Obermayer and Kunn-hope to merit the good esteem of our readers in the future with the assistance of our co-labourers, &c., &c." It is not long since Dr. Paschkis made his début in a similar fashion in the pages of the same journal on the retirement of Prof. Schnitzler. This is the fourth time in twelve years which proves that the life of a Vienna editor must be a hazardous one when we find his ardour spent in an average of three years. It is not, however, so strange when the circumstances are examined of the editors' daily performances. They are all busy practitioners who take to this literary work as a sort of "extra" which ere long becomes tedious to themselves.

Epi-desmitis Perforans Sanata.

For some years past we have been flooded with terms "more appropriate" for "perfect division and definition' in our classification of disease that renders it difficult for the casual reader to recognise what he is perfectly familiar with. Epidesmitis $(\tau a \ \epsilon \pi \iota \delta \epsilon o \mu a \ appendix)$ is no exception to the rule as Eiselt is persuaded that this

is the more correct term for the disease we have lately defined as appendicitis, processitis vermisculitis, coculitis, &c.

He records a case of this kind, which came under hisnotice in November last, and recovered without any surgical interference.

A scholar, et. 14, became ill on November 7th; on the 11th pain in abdomen, diarrhea, vomiting, and sore throat commenced; on 15th he was brought to hospital.

On examining the patient, follicular angina was discovered, the abdomen regularly distended, with amphoric percussion, the diaphragm was raised to the fifth rib, the lung percussion normal, while liver and spleen could not be defined, except posteriorly, where the liver was percussed under the right shoulder blade. Fever, vomiting of a bitter, greenish fluid, with great pain in the abdomen, aggravated by movement were the dominant symptoms. Owing to the great abdominal distension, no further palpation could be made in the lower part of the body, but it was assumed that the peritoneal cavity was filled with gas or pneumo-peritoneum.

The history of this case was at first somewhat obscured, as nothing could be elicited in the way of typhoid ulceration or other causes which might lead to perforation, and are often due to peptic, tuberculous carcinomatous, and other forms of ulcers, as direct erosion of the bowel is rare. None of these causes being probable, the origin was supposed to have proceeded from the appendix.

As no typhoid symptoms had preceded the illness, there was constipation prior to the attack, with slight pain, which we may assume to have oeen typhlitis. There are cases on record, however, where ambulant typhoid has proved fatal in the ball room, but these usually occur in the third week of the attack, when an apyretic condition of the temperature is observed. In the case of this scholarthe tympanitis, vomiting and collapse continued up to November 21st, when the vomiting ceased, and the distension of the abdomen suddenly disappeared.

On November 25th distension and pain in the abdomen reappeared, with an elongated tumour in the cæcal region. On November 27th the diaphragm was raised to the level of the sixth rib. Clysma were occasionally given with sedatives for the pain up to the 28th, when the fever subsided, though it slightly recurred on December 5th. The cæcal tumour gradually disappeared after this till it reached the dimension of 6 ctm. long without pain, and was immovably fixed at Poupart's ligament, when the patient again recovered his usual health.

It is fair to assume from these symptoms that the perferation took place in the vermiform process and that gas, probably coprophytic, escaped into the peritoneal cavity without producing exudative diffuse peritonitis, which finally became absorbed after the perforation had closed.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

REMOVAL OF CARCINOMATOUS GLANDS FROM THE AXILLA. NO APPARENT PRIMARY DISEASE.—Mr. ANDERSON operated for the removal of a mass of carcinomatous glands from the right axilla. The patient, a healthy-looking woman, et. 45, had noticed a growth in

the right armpit six months before; this continued to enlarge, and other growths made their appearance in the same region. There was no marked impairment of general health, and no sign of other disease in the body. The family history was negative. On examination a number of hard tumours, evidently glandular in origin were found filling the whole of the right axilla as high as the first rib. They were not adherent either to the skin or to the axillary walls and were but moderately tender on pres-The supra-clavicular region was normal. A close examination was made of the mammæ and of the whole trunk, but no abnormality of any kind could be detected. The axilla was freely opened up, and the tumours, together with the axillary fat, were completely removed leaving the vessels and nerves cleanly dissected, and clearing the whole of the connective tissue from the axillary portion of the pectorals and subscapularis. On section of the structures removed the glands were found to have undergone scirrhous transformation, but the disease had not extended beyond the capsule of the gland in any case. The operation was attended with little bleeding, and no apparent shock. Subsequent microscopic examination confirmed the diagnosis of carcinoma. Mr. Anderson remarked that the case was one of great pathological interest; there could be no doubt as to the malignant nature of the tumours, and that the growth was carcinomatous and not sarcomatous, but no primary disease could be discovered in any of the parts drained by the affected glands. Suspicion pointed towards the right breast as the most probable seat of primary disease, it even became a question whether it was not desirable to remove the mamma as a precautionary measure, the possibility of the existence of small dessiminated foci, not yet appreciable to the touch. having to be considered; it was decided, however, not to take this step. A close watch would be kept on the patient, all the regions drained by the axillary glands would be retained under notice, and a further operation would be performed should any justifying lesions reveal themselves. He was not aware that any similar case had been recorded. Theoretically, he said, it appears impossible that an epithelial growth should originate in the lymphatic glands, and the probabilities still were that some primary disease would ere long become manifest, but there was nothing in the present aspect of the case that justified further interference.

It is now four months since the date of the operation. The wound healed by first intention, the patient's health remains good, and there is no sign of d sease in the mammæ or in any other part; the axilla shows no recurrent growths, and the supra-clavicular region remains free from disease. It is still early, Mr. Anderson thinks, to pronounce a dictum upon the case. The patient will be watched closely, and should she remain free from malignant growths for a twelvemonth there will, he considers, be an interesting field for pathological speculation.

Removal of a Tumour of the Ascending Ramus of the Lower Jaw.—The same surgeon operated on a boy, æt. 14, a fairly healthy-looking lad, who had noticed six months before a swelling of the left side of the lower jaw. This gradually increased, but without causing much pain or inconvenience. The tumour involved the whole of the ascending ramus up to the sigmoid notch. It was fusiform in shape, about two inches in thickness from without inwards, the inner surface was hard as though covered with a shell of bone, the outer surface

was soft, no glandular enlargement was found, and there were no indications of secondary deposits. Mr. Anderson commenced the operation by making an incision from the angle of the mouth downwards to the angle of the jaw, then curving upwards in the direction of the mastoid process; the flap so formed was reflected with the parotid and the superficial fibres of the masseter, which, apparently uninfiltrated were stretched over the tumour; the bone was sawn across from behind the second molar tooth downwards in front of the insertion of the masseter, this was then seized, turned upwards, the fibres of the internal pterygoid being cut across; the coroncid process was divided with bone forceps, and the bone was disarticulated from the inner side; the diseased portion of bone could now be detached by a few touches of the knife, leaving the parotid intact. The bleeding vessels were secured as soon as divided, the loss of blood being only molerate. On examination of the tumour it appeared to be an endosteal sarcoma, which had distended the bone on the inner side, but had escaped from it on the outer side; it presented the characters of a myeloid, and was afterwards found to be of this nature. Mr. Anderson said that in the absence of infiltration of the tissues the operation was not one of great difficulty, and the prognosis, on the diagnosis of endosteal sarcoma, was decidedly favourable. The chief difficulty would be, he considered, in relieving the deformity which would arise as a result of the unbalanced action of the masticatory muscles of the opposite side; it was a problem that at present remained unsolved to keep the teeth of the lower jaw in their correct position with regard to those of the upper, although Mr. Birnie and others had devised various ingenious appliances, and this would be a matter for consideration during the following weeks in the present case.

Vital Statistics.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 19.5 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of the year 1899.

Birkenhead 22, Birmingham 22, Blackburn 15, Bolton 19, Bradford 16, Brighton 13, Bristol 15, Burnley 18, Cardiff 15, Croydon 11, Derby 18, Dublin 31, Edinburgh 26, Glasgow 33, Gateshead 24, Halifax 22, Huddersfield 13, Hull 14, Leeds 18, Leicester 15, Liverpool 25, London 19, Manchester 23, Newcastle-on-Tyne 23, Norwich 14, Nottingham 17, Oldham 22, Plymouth 15, Portsmouth 19, Preston 22, Salford 19, Sheffield 20, Sunderland 27, Swansea 21, West Ham 15, Wolverhampton 22. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were: -From measles, 1.2 in Manchester, 1.4 in Oldham, and 1.9 in Bolton; and from whooping cough, 1.0 in Gateshead, 1.1 in Nottingham and in Halifax, 1.3 in Bristol, 1.5 in Swansea, and 2.2 in Preston. In none of the large towns did the death-rate from scarlet fever, from "fever," or from diarrhea reach 1.0 per 1,000. The 90 deaths from diphtheria included 32 in London, 9 in Leeds, 8 in Sheffield, 6 in West Ham, 5 in Birmingham, 5 in Leicester, 5 in Liverpool, 3 in Glasgow, and 3 No death from small-pox was regisin Portsmouth. tered in any part of the United Kingdom.

A Very Small Baby.

THE Boston Medical Surgical Journal says there is at present at Gouverneur Hospital a female infant reported to be perfect in its development in every respect except as regards size; at the age of two months she weighed but 322 ounces. When born her weight was only 16-ounces.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 15, 1899.

DIRECT REPRESENTATION AND THE GENERAL MEDICAL COUNCIL.

THERE can be no question that the recent dramatic case of the General Medical Council versus Hunter, with its tragedy of main motive, of climax, and of sequel, has sunk deep into the minds of the profession. When the time comes for the Council to meet once again we must look to the Direct Representatives to insist upon threshing the matter out, as far as it may be possible, in the teeth of an obstructionist majority. There are points involved in this case that must be publicly investigated, or a great number of medical practitioners will be for ever exposed to a ruinous presecution similar to that which their elected representatives on the Council have been induced to sanction in absolute ignorance of the essential facts of the case. To prosecute a licentiate of the Society of Apothecaries because he chooses to style himself a physician is to beat the air and to harass the loyal soldier within the camp while treacherous hordes of outlaws are allowed to plunder both public and profession at their own sweet will. We ask, as many have asked before, why ie all this? What condition of government permits such a gross travesty of the ordinary rules of common sense to sway the destinies of a cody of educated men, from whom Government has exacted the most stringent proofs of special technical knowledge? The only answer we have ever seen advanced that deserves serious consideration is that by constitution the Council is an autocratic bureau, a body nominated mainly by Government and by the medical corporations, to the exclusion of the elective principle. Could we imagine a popularly elected governing body neglecting the quacks and turning

their attention to the discomfiture of their own duly qualified and registered members? The decision of the Court of Appeal in the Hunter case has added to the absurdities of the position, for so far as we can grasp the situation Her Majesty's judges have declared that no one but a doctor of medicine may call himself physician; at any rate, a man holding the diploma of the Royal College of Surgeons and of the Apothecaries alone is not entitled to the titles of either "Doctor" or "Physician." If the Council be logical it will go the round and spend the funds provided by the medical profession in a prolonged series of domestic prosecutions founded on this or that similar fatuous hair-splitting, which puts money in the pockets of the lawyers, but confers not one morsel of good upon any other person in the realm. reviewing the past history of the General Medical Council it is impossible to escape from the conclusion that the policy of that august body is out of touch with the sympathies and the interests of the profession they are supposed to govern. A simple remedy for the present state of affairs, which the Hunter incident has rendered well-nigh intolerable, may be sought in an in mediate increase of the Direct Representatives a reasonable demand that has now been urged upon the Council for years past. But it is always better, where feasible, to make the most of existing machi nery, and it is quite likely that the University representatives should legally be elected by graduates, and not nominated by each individual Senator. If this point were established, a great step would thereby be accomplished towards a broader electo ral basis for the Council. We fear such a que stion lies somewhat outside the field of the Medical Defence Union, the quarter to which we are beginning to turn for help in every strait. The want of organisation among the ranks of medical practitioners renders it well nigh hopeless to look to them for any initiative. For all that, the question of choosing their own Council representatives might be usefully discussed by some of the graduates' clubs that exist in various parts of the United Kingdom. Will some Scotch or Irish university lead the way P

HISTORY BASED UPON DIET .-- II.

AT the present time Americans eat more meat per head per diem than any other civilised people, closely followed by the people of our islands. Then come the Germans, followed by Austrians, French, Russians, &c. In almost the same order the brain power, as shown by inventive genius and mental acuity, may be arranged. The genius of the German people, so fruitful in output of material, tends rather to the laborious expansion of ideas and discoveries initially conceived by the more active cerebral centres of the Anglo-Saxon than to initial invention. The German brain consolidates and perfects what the Anglo-Saxon suggests. The brain of the greater flesh-eater conceives what the other is better able to examine and prove after suggestion. It is easy, of course, to instance numberless contra-

dictory examples of individuals personally endowed with unusual talent, either through heredity, owing to environment, or even to what must be regarded as pathological development. But if the achievements of nations be taken en masse the characters of their work represent the results of diet. It is almost the fashion to sneer at food as a factor in human acquirements. Many instances of great men who have showed an utter disregard for the pleasures of the table and the manner of their nourishment can be mentioned. Still brain tissue is the outcome of food; its quality the outcome of the food's The nature of the food eaten influences quality. the meal-time. The Briton and American enjoy a good breakfast, they deposit cash in their bodily bank on which to draw for the purpose of paying ready money for the energy made use of in the course of the forenoon's mental and physical work. They supplement the withdrawal after midday, and again at night. The amount deposited overnight is added to next morning, and the day's work can be paid for without stress. The common custom of many nations to delay their first solid meal until near mid-day involves overdrawing their balance in the forenoon, replacing the deficiency at mid-day, but only to overdraw it again later, unless, as often is done, another large deposit is made before the first has been properly dealt with and distributed; while, after this, a long period elapses before any further addition is made, during which time their outlay again depletes their intake. One result of this method of paying at the end, rather than drawing upon cash already provided, is the common auto-intoxication from overabsorption of digestive products after the midday meal. The interval from the last intake of food has been so long, the debit balance so great, that rapid absorption leads practically to proteose intoxication. Somnolence comes, and very frequently a universal suspension of work for one or two hours is necessary. The interval, or even siesta, after the midday meal, common even in parts of Germany, results from this. The natural result is apparent in the greater power for rapidity in work done, should the worker be untrammelled by restrictions as to meal-times put on him by others. To our personal knowledge some of the best medical authorities upon dietetics in Germany follow our example, and partake of a much more generous breakfast than the roll and coffee usual there, and for much the same reasons as are put forth above. As the body is nourished by the food taken in; and. as the nature of the food, while exercising no influence upon primitive and generic characteristics, and but little upon the lower nervous attributes of early acquisition, appears to affect very markedly the range and activity of mental processes; so dietetical economy must influence the story of a nation's history in the World, must mould the predominant characters of the race, and shape its destiny more intimately than our public politicians might care to allow. Climate governs diet; diet governs human minds; progress and predominance must rest with

those races who dwell where they can consume the results of "breeding-in" among animals. But the more brain-helping food than their neighbours, provided they fall not into ways of luxury and foreign habits as to food, inapplicable to the degree of latitude near which they But it is not the trivial forms in which the necessary food stuffs are consumed and appreciated which affect nations, but the much wider question of their actual source. Animal proteids and extractives in any form, compatible at least with the process of healthy digestion, serve no more useful purpose in rendering perfect the physical development of man, than those substances obtained from the vegetable The lower cerebral faculties, touch, sight, hearing, the reflex and trophic powers, are probably as highly organised, though they may be, when circumstanced differently, educated to a keener or duller pitch. The more mechanical mental processes, the condescension to present and petty details, the qualities of fear, love, and endurance of pain, these may not differ markedly; but the greater powers of governing and swaying others and looking beyond the actual surroundings or the details of the present, to the possibilities of the future or to the discovery of new laws and facts; such powers are dependent, we believe, upon the actual source of the body's nutriment. Beef-eating Britons invented the loom and steam-engines, discovered the practical powers of electricity, introduced vaccination, antiseptics, produced a Shakespeare, founded the Mistress of all Parliaments, and have succeeded marvellously in the art of governing other peoples. Their greater brain power has conduced to the strengthening of their bodies by various games and athletic exercises; the excess of nervous activity seeking such outlets.

THE PROVINCES AND MEDICAL PROGRESS.

LONDON possesses no monopoly in human intellect, nevertheless it deservedly enjoys the reputation of possessing most that is best in this regard. No one can dispute that the environments of a Londoner are precisely those which compel the development of the intellectual, as opposed to other faculties. The speed of life, both mental and physical, is for this reason much greater in the metropolis than elsewhere. The proof that this is so is furnished by the necessity which exists for annually recruiting the populafrom country-born persons. The intermarriage of Londoners does not result, as a rule, in offspring whose physique even under the best circumstances can generally be said to attain to a normal standard. Indeed, there are some authorities who go further and state that the intermarriage of Londoners could not be continued beyond the third generation, inasmuch as by that time most of the persons concerned would be dead, or those that were living would be mostly imbeciles. To a large extent, however, this must be a matter of speculation. Nothing absolutely certain is known upon the subject, nevertheless the statement receives some support from the facts which we possess concerning

discussion of these interesting questions need not detain us now; the point to which we desire to draw attention is the comparison which has recently been made between the provinces and London in relation to the progress of medicine and surgery. In such a matter, of course, there cannot be any cause or room for rivalry. Clearly, it is immaterial in what part of the kingdom a great discovery in medical science is made. And yet Dr. Priestley Leech, in a recent presidential address delivered before the Halifax and District Medical Society, would seem to imply that some competition in this connection exists. He even definitely claims that the provinces have earned a position equal if not superior to that of the metropolis in the advancement of medical science, and he further avows that "What the provinces think to-day London thinks to-morrow." paraphrasing a well known political saving, is by no means imaginative so far as the matters medical and surgical of the past are concerned. Illustrative instances are thus given of the discovery of chloroform anæsthesia by Simpson in Edinburgh, of the birth of Listerism in Glasgow, of the provincial origin of the operation of ovariotomy, and of the work of McEwen. of Glasgow, Ogston of Aberdeen, and many others. Furthermore it is pointed out that to the provinces belong the work of Graves, of Dublin; Sir Dominic Corrigan, Sir William Roberts, late of Manchester, Christison and Hughes Bennett, of Edinburgh; also Syme, Liston, Sir James Clark, and the immortal Jenner, the discoverer of vaccination. Again, as if to further clinch the argument, it is shown that many successful and renowned metropolitan physicians and surgeons are provincial men. the explanation given of this being that "London is the Mecca of the medical and surgical pilgrim, just as it is of the literary pilgrim." All that the writer says, of course, is perfectly true. Outside the metropolitan area the members of the profession who have contributed to the advancement of medical science have been many and their work has been great. But because this has been the case in the past, it does not constitute, in our opinion a reason for drawing an invidious comparison between the original work of London and provincial physicians and surgeons. To attempt to establish a rivalry in this matter, and attach importance to the locality in which the work of scientific men is first made known, is not suggestive of the spirit of high ideals which should snimate those who work at science for its own sake. What can it matter whether a valuable discovery in medical science is made in London, Dublin, Edinburgh, or some other town in the Kingdom, beyond the fact that mankind benefits by its application? It is not the man, but his circumstances, which usually determine the locality in which his life work shall be carried out.

A SAD fatality occurred last week near Richmond, where Dr. Hudson Hairsine, of Sungate, Hook, was killed by being thrown out of his trap, a friend, Mr. Scott, being at the same time severely injured.

Rotes on Current Topics.

Influenza Again.

THE recent warm, damp weather appears to have paved the way to an epidemic of influenza of the classic type, though fortunately of a rather mild character. It is more especially in the metropolis that the outbreak has made itself felt, and the caseshave been very numerous, far more so indeed than for two or three years past. Unless more seasonable weather characterises what remains of an exceptionally mild winter the epidemic may run on into the spring, a prospect which, if not altogether disconcerting to medical practitioners, cannot fail to entail grave inconvenience on the public. The prevalence of a disease such as influenza, even of a mild type, is attended by very disastrous results to friendly societies and similar provident associations, the average weekly sick list being hugely exceeded in the aggregate without warning, and to the detriment of their finances. We shall no doubt witness a corresponding increase in the death-rate, for although the disease may only temporarily disable persons of average vitality, the debility which it engenders is quite sufficient to turn the scale in the case of those whose hold on life is enfeebled by age, pre-existing weakness or disease. Attention has been called to the prevalence of a disease resembling influenza among cats, and though it must be difficult to identify it with that from which so many human beings are just now suffering there is enough to justify the warning to discourage intimacy on the part of children with animals recognised to be suffering from what isvulgarly described as "cold."

Women Dipsomaniacs.

OF all the problems before the busy practitioner, it may safely be asserted that none presents more knotty and complicated issues than that of secret drinking among women. For reasons that are more or less apparent, the disastrous habit of intemperance assumes peculiar characters in the sex mentioned. The element of secrecy is exaggerated, the moral control of the victim more surely sapped, and the hope of future amendment more forlorn. For the medical man, therefore, when called in to such a cese, decide upon what is the best course to pursue, with a due regard to the interests of his client, is always a momentous one. assume an attitude of honesty and tell the patient outright that her symptoms are due to alcohol, which must be no longer consumed in any shape or form, it is always certain that he will thereby lose a patient. If, on the other hand, he temporises, and allows her to feed the flame of her craving with small doses of stimulants, he knows that the last lingering chance of reform is thereby destroyed. To disclose the state of affairs to the patient's friends, and to ask their help in cutting off supplies, is rarely of the least use. Supposing the patient to be mother of a family, how can one send her away to a private "home" for inebriates? A clear and concise guide to the medical

man, as to the best course to pursue with female alcoholics, would be of the greatest practical value.

Tonsillitis and Rheumatism.

THERE is an evident relationship between the rheumatic diathesis and a tendency to tonsillitis, at any rate to the extent of coincidence. It cannot however, as yet be affirmed that there is any closer association, because both rheumatism and tonsillitis are such common ailments that mere coincidence does not per se go far to establish anything in the nature of a direct pathological association. It is asserted that faucial erythema is an initial manifestation of rheumatism, and may, indeed, be the actual primary lesion. Many cases are recorded in which endocarditis has followed a non-scarlatinal tonsillitis unac companied by joint pains, and in many other instances the tonsillitis has been followed by an attack of arthritis or chorea. All these cases go to prove that rheumatic subjects are specially prone to faucial and tonsillar inflammations, just as they are known to be prone to certain forms of cardiac disease, chorea, &c. If we ask patients suffering from follicular tonsillitis or quinsy, whether they, or other members of their family, have suffered articular rheumatism we shall find that in a very large proportion of cases the answer will be in the affirmative. It would be odd if it ultimately turned out that rheumatism is a microbial affection whereof the point of entry was, in many cases, if not in all, the pharyngeal mucous membrane and its glands. So strongly is the interdependence of the two conditions believed in by some authorities that we are invited to institute the salicylic treatment in every case of sore throat of the types known to occur in association with rheumatism with the object of averting subsequent arthritic manifestations, but we are not prepared to say that the suggestion receives much support from clinical experience. generally conceded that this treatment produces no very tangible effect on the course of the tonsillar nffection and attacks of articular rheumatism have been known to supervene in spite of it. How often the treatment is the means of averting a rheumatic explosion must remain matter for surmise, but the subject is one which merits careful consideration and further clinical observation.

Purulent Ophthalmia and Gonorrhœal Rheumatism.

PURULENT ophthalmia in the new-born is almost always of gonorrheal origin, and there is no obvious reason why a gonococcic inflammation of the conjunctiva should not occasionally be followed by the articular manifestations which are, in rare instances, associated with gonorrhea involving the urethra. In a paper recently brought before the Royal Medical and Chirurgical Society by Mr. Clement Lucas, a number of cases were related in which arthritic manifestations had supervened in the subjects of ophthalmia neonatorum. The ophthalmia usually made its appearance on the third day after birth, and

the joint disease towards the end of the second or during the third week of the ophthalmia. knees were the joints most frequently affected, especially the left, but the mischief was not limited to the knee, for the wrists sometimes suffered. It is noteworthy that complete resolution was the rule in these cases within from three to five weeks. contrasting strangely with the course of the disease in typical gonorrheal rheumatism. Bacteriologica examination showed that the gonococcus of Neisser was the cause of the ophthalmia and of the joint disease. but in the rare cases of suppuration of the joints other pyogenic organisms were also present. It is not denied that this complication is rare in association with purulent ophthalmia, but this may possibly be explained by the greater ease with which the secretion escapes from the conjunctival surface as compared with its tendency to accumulate in the male urethra, and this explanation may also throw some light on the infrequency with which women suffer from this arthritic sequel of gonorrhea. Suppuration in any part of the body may be followed by inflammation of a joint, and this is not invariably the result merely of the passage into the circulation of the products of inflammation, seeing that the pathogenic organism itself has been isolated from the fluid in the joint. The fact that the relationship between the conjunctival affection and the joint trouble has been but rarely noted does not, of itself, militate very strongly against its existence, for until we have been taught to look out for them, such associations usually escape notice, especially as the treatment of the eye affection falls into the hands of the specialist, while the joint trouble comes under the cognisance of the physician. Now that attention has been directed to the possible existence of an inter-dependence of the two affections, clinical observers will be enabled to scrutinise their cases more closely, and thus establish the validity of the view put forward by Mr. Lucas.

A Simple Method of Curing Aphonia.

A READY means of curing functional aphonia is suggested by Dr. Abrams in the Therapeutic Gazette. He marks with a pencil on the side of the neck corresponding to the paralytic vocal cord the point where the superior laryngeal nerve sends its internal branch to the larynx. This, it will be remembered, is the sensory nerve for that organ, and he applies at the spot indicated a spray of chloride of methyl or other local refrigerant until the freezing process is complete. The relief is in most cases immediate and phonation, which was before difficult or impossible, can be performed with perfect freedom and painlessness. The relief is in some cases only of short duration, and in these the process of freezing must be repeated one or several times. This method, he adds, is also of value in neuroses of the larynx, such as laryngismus stridulus, spastic aphonia, and in the laryngeal crises of tabes. He explains the action of the refrigerant on the assumption that the cold acts as a shock inhibit

ing nerve action for a time. The sedative action of refrigerant sprays is well known in other neuroses, as for example in neuralgia, for which stypage, the name given in France to the linear application of extreme cold, renders signal service. The treatment is equally applicable to the painful manifestations of peripheral neuritis, sciatica, and the like, and it merits more attention than it has hitherto received in this country. It is at once cheap, prompt, and effectual. All that is necessary is a cylinder of anestile provided with a fine jet, and this is drawn along the line of the irritated nerve until relief is obtained, a process which usually does not take more than a few seconds.

The New Consumption Cure.

A PARAGRAPH has been going the round of the Press announcing that the managers of the Brompton Hospital for Consumption have decided to inaugurate the "new" cure for consumption, viz., the openair treatment. Now this is probably the oldest treatment devised for the disease, and after many vicissitudes it has once again come to the fore, but to call it a new treatment is, of course, a flagrant absurdity. Its usefulness in suitable—that is to say, not too advanced-cases cannot be questioned, and there could hardly be a better place in this country to carry it out than on the very eligible property belonging to this wealthy institution in the Isle of Wight. As might have been anticipated, the announcement of the new departure is coupled with a statement that the managers are obliged to sell stock to provide the money, pending public contributions to the extent of six or seven thousand pounds. One advantage of this treatment is that it need not entail any great expense. The accommodation required is of the slightest, and there are no heavy items on account of extensive buildings, such as have largely contributed to absorb the more than liberal donations of which the Brompton institution has from time to time been the recipient. It looks as if "consumption camps" were about to become a national institution, but there is no manifest advantage in making them large; on the contrary, the moment they exceed the number of patients who can be efficiently looked after by a single medical superintendent the tendency is all the other way.

M. Haffkine and the Plague Commission.

After the virulent attack by Colonel Lawrie upon M. Haffkine's inoculation treatment of the plague, it is pleasant to refer to the evidence of the latter, given before the Plague Commission, and learn the truth about his serum. In the first place, M. Haffkine admits that his serum is not a cure for the plague. He even candidly asserts that, "on comparing the mortality among those who passed through his hands with those who were treated in the ordinary manner, it was found that the mortality was greater among the patients who passed through his treatment." Candour on the part of a scientist could scarcely go further than this. On the other hand, he claims

with a confidence bred from experience, that his serum is a prophylactic, and that, given a healthy person inoculated according to his method, it will prevent him contracting the disease. He lays great stress upon the fact of the previous healthiness of the inoculated person; so much so that he states that his serum cannot prevent or modify the disease if the latter develops within a few hours of inoculation. It is reported that M. Haffkine will come to England in May next with a view of laying his results before the Royal Society.

A Wily Testator.

CONSIDERABLE interest has been manifested in France in respect of the testamentary disposition of a well-known theatrical author called d'Ennery. Not long before his death he made a fresh will disinheriting his immediate relatives, and constituting as universal legatee his adopted daughter. As the wily old gentleman foresaw litigation by his disappointed family he actually took the precaution to nominate a commission of medical experts to inquire into his mental condition, and when they had signed a certificate of compos mentis he put his intentions into words. It is difficult to see what loophole he has left for undermining his testamentary dispositions, and he has set an example which eccentric and aggravating testators may perhaps find it well to follow in the interests of their estates.

A Sanitary Oath.

A NEW YORK police magistrate has set a good example in the matter of oath-taking by ordering the Bibles then in use to be discarded, denouncing the custom of kissing them as "dangerous to health and unspeakably filthy," and, as a result of this magistrate's protest, the New York courts are being supplied with "hygienic Bibles," the covers whereof are made of celluloid, which is kept clean and free from infection in accordance with antiseptic principles. Following on the same line the Board of Health has ordered persons in charge of public telephones to wash the ear and mouth pieces daily with a disinfectant, a precaution which ought to be made compulsory here as soon as the use of this instrument becomes as general as it ought to be.

Another Death Sentence Farce.

JANE WHITE, the nurse who was convicted last week of causing the death of a woman in London by the performance of an illegal operation, was subjected to the repulsive form of being sentenced to death by the judge, in spite of the fact that in the present state of public opinion there is no possibility of its being carried out. We have no sympathe, needless to say, with delinquents of this type, but it is urgent that this melancholy judicial farce, consequent upon the indefensible doctrine of constructive murder, should be abolished. Every case that occurs of this kind renders its absurdity more glaring, and we trust that the present session of Parliament will put an end to what is universally recognised and described as a judicial scandal.

New Poison Regulations for England.

THE Privy Council, on the requisition of the English Pharmaceutical Society, has adopted the following regulation for the guidance of chemists:-

"1. That in the keeping of poisons, each bottle, vessel, box, or package containing a poison be labelled with the name of the article, and also with some distinctive mark indicating that it contains poison.

"2. Also that in the keeping of poisons, each poison be kept on one or other of the following

systems, viz.:—

'(a) In a bottle or vessel tied over, capped. locked, or otherwise secured in a manner different from that in which bottles or vessels containing ordinary articles are secured in the same warehouse, shop, or dispensary; or

"(b) In a bottle or vessel rendered dis-tinguishable by touch from the bottles or vessels in which ordinary articles are kept in the same warehouse, shop, or dispensary; or

'(c) In a bottle, vessel, box or package kep in a room or cupboard set apart for

dangerous articles.

"3. That in the dispensing and selling of poisons, all liniments, embrocations, and lotions containing poison be sent out in bottles rendered distinguishable by touch from o dinary medicine bottles, and that there also be affixed to each such bottle (in addition to the name of the article, and to any particular instructions for its use) a label giving notice that the contents of the bottle are not to be taken internally.

The Conscientious Objector.

It is comforting to be assured, as we are by a contemporary, that the state of affairs as regards exemptions from vaccination is not so bad as might have been feared. It would appear that a good many of those who obtained exemption did so to be in the prevailing fashion, and to save themselves trouble. Having appeared in Court and been granted the exemption, numbers of them did not take the trouble to call for the official certificate which is now invalid by lapse of time. The vaccinations also have shown a remarkable increase in number in some of the worst districts.

Beautiful for Ever.

THERE is probably no branch of quack practice that brings in a greater amount of solid pelf than that which deals with personal appearance. To preserve, to magnify, and even to create beauty is the bait that attracts clients above all others. cure and care of the skin, hair, teeth, nails, and the removal of blemishes fall within the scope of these cosmetic operations albeit nowadays a good many of them are performed by qualified medical men. Within recent years the prevention and the treatment of baldness and prematurely grey hair, so long the harvest field of the charlatan, have come within the range of scientific medicine. To a certain extent a similar observation applies to the complexion, which may be benefited by many direct and indirect As a broad general rule, however, it procedures. may be said that more skins are ruined by interference than by neglect. The constant use of certain irritating soaps, toilet vinegars, and powders to be found in nine out of ten genuine toilet outfits would, in

the course of time, prove fatal to the well-being of any complexion. So long as human nature runs on its present lines it seems likely that the tradesman who panders to vanity by professing to help people to keep level with Father Time will be usually foremostin the road to fortune.

Congress Against the Abuse of Alcoholic Liquors.

THE Seventh International Congress against the abuse of Alcoholic Liquors will be held in Paris in April, and a very extensive programme of matters for discussion has been arranged. Among the subjects to which special attention will be devoted will be: the temperance cause in the primary schools, alcoholism among workmen in urban and country districts, the prevalence of alcoholism among native races and its prevention. The drink problem is one eminently suitable for international discussion, inasmuch as in every part of the world it demands attention. Although intemperance cannot be abolished by law, there is yet much which can be done by voluntary effort to counteract its evils, and no nation can afford to lose sight of the fact that the education of the community in the principles of temperance is a wise policy to encourage and endorse.

Royal Munificence.

A NOBLE act in connect on with the movement for the prevention of tuberculosis has been pointed out by the Local Government Journal. The sum of £25,000 was raised as a national tribute to the Queen Regent of Holland, when Her Majesty relin quished the position at the recent coronation of her daughter. With womanly generosity and pity, however, Her Majesty directed the sum to 'e employed in the building of a sanatorium for phthisical patients, and not content with this act of munificence, she has also given a splendid site on her own property for the proposed institution. Such openhearted generosity as this on the part of the Queen Regent of Holland forms an object lesson which might well be taken to heart by wealthy persons generally. Moreover, apart from the munificence of the gift, no one can fail to be struck with the admirable object of its disposal.

A New Medico-Ethical Society.

THE practitioners of the East-End are to be congratulated upon the success of the East London Medical Protection and Medico-Ethical Society which they founded a year ago. One of its objects is to compile black lists of patients who fail to discharge their debts; another is to deal with cases of unprofessional conduct, and during the past year, despite opposition, the society has succeeded in obtaining adequate representation (25 per cent.) of the medical profession upon the committee of the proposed East Ham Hospital. Thus the society may be held to have well established its raison d'etre, and there is no doubt that it is eminently worthy of the support of all East-End practitioners. Up to the present, we believe, it consists of nearly a hundred

members. So far as it goes this is a satisfactory commencement, but there must be still a large contingent of practitioners in the district, whose interests it would be to join the Society.

The Taking of Snuff.

It is likely that a few people are aware of the extent to which snuff is still consumed in Great Britain. Many large and flourishing manufacturers of that article are in full swing in various parts of the United Kingdom. The habit of "snuffing" is usually regarded as a characteristic of byegone generations, but a little inquiry will show that the custom not only survives among the derelicts but is also continually finding recruits among the young men of the present day. Judging from report snuff seems to be enormously adulterated. Some years ago a defendant, charged with an offence of that kind, explained that there was really not a particle of tobacco in his precious commercial compound, which consisted simply of tan and powdered roasted apples, with an added aroma skilfully derived from ammonia and essence of geranium. Before that brilliant essay the average fraudulent tradesman may well pale with envy and hide his diminished head. When our local boards bring their energies to bear upon the really useful and necessary duty of a proper control of the purity of food and drugs it would be well for some of the inspectors to overhaul the snuff stores of their districts. From a health point of view lead and many other harmful adulterants are often added, and in the form of snuff run every chance of absorption into the system.

A Bacteriological Squabble.

THE popular lecture which Mr. Bousfield, the bacteriologist for the district of Camberwell, recently delivered at the invitation of the vestry, has since proved the occasion of scenes of the most indecorous kind in the bosom of that body. They had voted £10 for the expenses of the lecture, which appears to have .degenerated into a sort of soires whereat refreshments to the tune of £20 or so were consumed, which the vestry was asked to make good. As is not infrequent in discussions about trivial subjects in these local parliaments, the proposal proved the starting point of an exchange of personalities which culminated in the expulsion manu militari of one of the members, after which the deficiency was voted, though not without a protest against the extravagance of the committee responsible therefor.

The Colour of Negro Babies

This much controverted question has—let us hope—been settled by the statement of a well-known authority, who affirms, apparently on the strength of experience, that "pure negroes when born are pink like young rats, and at the end of three or four months they gradually become black." We trust this may settle the question, which, after all, possesses but a mediocre interest for the inhabitant of these blest isles where coloured people are so rare that, if possessed of means, they are positively lionised. So

long as these babes ultimately become black, so that they cannot pass themselves off as British born, we have no right to complain.

Public Analysts.

A SERIOUS, though probably unwarranted, charge against the integrity of public analysts was made last week in the Barnsley Police Court by a shopkeeper who was prosecuted, on the certificate of the public analyst, for selling fraudulent ginger. He alleged that he had tried in vain to obtain an independent opinion from another public analyst, but that he found that there is an understanding among the analysts that no one was to give evidence against a public analyst's certificate. He therefore, asked the magistrate to send a sample to Somerset House, which was done.

The Professorship of Pathology at Cambridge.

On Saturday last Dr. G. Sims Woodhead was elected to the post of Professor of Pathology at the University of Cambridge, in succession to the late Dr. Kanthack. Dr. Woodhead has for the past few years held the appointment of Director of the Pathological Laboratories of the Royal Colleges of Physicians and Surgeons, at the Examination Hall building on the Embankment. He is well known as an original worker, and has fully proved himself competent to undertake the responsible duties of the Professorship to which he has just been elected. We congratulate him upon his appointment and the University of Cambridge upon securing the services of so able a pathologist.

Medical Officers for West Africa.

THE Colonial Office has advertised for medical officers for temporary service on the Gold Coast and also with the Niger force. The salary offered is £350 with quarters, or an equivalent allowance, and free passage out and home. The officer will also receive £100 at the end of his first year of service, if he be approved of, and will have six months leave for every twelve months served on the coast.

Gastric Origin of Rickets.

A French observer claims that rickets in children is due to abnormal conditions of digestion; that the secreting function is extremely defective, as well as the quality of the secretions; and that there is especially a lack of free hydrochloric acid. The organism suffers from the want of properly digested nourishment, and the stomach is the seat of abnormal organic ferments generating acids, principally lactic acid, which affect the bony tissues unfavourably, especially as respect the phosphates.

A SUSPICIOUS death has occurred at Middleburgh, in the Transvaal, the victim being an Indian who presented symptoms suggestive of plague, and a movement is on foot to restrict the immigration of Asiatics.

Re-Definition of Dispensary Districts in Ireland.

A GOOD deal of local excitement has been produced in various parts of Ireland by the distribution of the Dispensary districts which the new sub division of the country into counties, districts, and unions has rendered necessary. Medical officers find that slices are taken from neighbouring districts and added to theirs, or vice versa, and the balance of power greatly disturbed, additional work being added on or rivals introduced into what they have, heretofore, regarded as their preserves. Moreover, the poor find themselves precipitately handed over to new doctors, with perhaps the necessity of travelling longer distances to consult them. We cannot see how these troubles could have been avoided, and it seems obvious that the only means to a settlement of disputes will be by conference between the local guardians and committeemen and the Local Government Board which, we are convinced, are anxious to meet local opinion as far as possible. At all events it is clear that THE MEDICAL PRESS AND CIRCULAR is not competent to express opinions upon these purely local questions, as it has been asked to do in several instances.

The Parliamentary Outlook.

THE Government programme contains, practically, but one Bill, the Adulteration Bill, of special interest to the profession. No mention is made of any attempt to remedy the vaccination muddle of last year, nor is there any hint of the Re-Vaccination Bill which Lord Harris, on behalf of the Government, almost promised to Lord Lister last session. Private Bill legislation on medical or any other subject is in a worse pickle than ever. No more than six or eight Bills have a chance of being heard of in the House before Government seizes the private Members' days. Of course there will be opportunity, when the House is moved into Committee of Supply, to debate a variety of questions, and, thereby, educate the Government and the public, but no more can be expected than this.

THE last public function performed by the Countess of Elgin before leaving India for England was the opening of the Lady Dufferin Victoria Hospital for Women in Calcutta. The building is a very beautiful one, and with its modern arrangements, marble floors, white tiled walls, &c., bids fair to rank as the finest hospital for women in India. Miss Church, M.D., is the doctor appointed to this hospital.

PERSONAL.

Mr. C. B. Lockwood, F.R.C.S., has resigned his appointment as surgeon to the Great Northern Central Hospital.

A TELEGRAM from Constantinople announces the death of Mavroyein Pacha, private physician to the Sultan of Turkey.

THE Grand Duchess of Saxe-Meiningen has intimated her intention to attend the Tuberculosis Congress to be held in Berlin in May next. THE Senate of the Royal University of Ireland have appointed Professor Byers, of Belfast, as Examiner in Midwifery in the University.

Dr. Farquiarson, M.P. for Aberdeen, has been selected to act as chairman of the Scotch Liberal members in room of Sir Henry Campbell-Bannerman.

DR. CLIFFORD ALLBUTT, F.B.S., Regius Professor of Physic in the University of Cambridge, has been elected an Honorary Fellow of the Royal College of Physicians in Ireland.

A DISTINGUISHED Service Pension of £100 a year has been conferred on Sir Robert Jackson, F.R.C.S.I., Governor of the Apothecareis Hall of Ireland, in consideration of his long and brilliant services in the Army.

Dr. W. J. Collins, ex-President of the London County Council, has been appointed by the President of the Board of Agriculture to represent the Council on a Departmental Committee to inquire into the Diseases of Animals' Act.

A HALF-LENGTH portrait of the late Mr. Henry Lee, F.R CS, by Mr. James Sant, R.A., has been presented by his widow to the Royal College of Surgeons. Mr. Lee was formerly Member of Council, and Lecturer in Pathology and Surgery of the College.

Dr. A. C. Duffer, late House Surgeon to the City of Dublin Hospital, was the recipient last week on leaving of a very fine antiseptic operation case and an exquisitely appointed smoker's cabinet, presented as an expression of the esteem in which he was held during the whole time he held the office by the medical and surgical staff, resident students, ex students, and nursing staff.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

PROPOSED MEMORIAL TO THE LATE PROFESSOR COATS.—A meeting of the friends, former colleagues, and assistants of the late Professor Coats was held last week in the Faculty Hall, for the purpose of considering a scheme for erecting a memorial to the memory of the deceased professor of pathology. Principal Story presided and having briefly stated the object of the meeting, Sir William Gairdner moved a resolution, seconded by Dr. H. C. Cameron, which was carried unanimously, that a memorial be raised to the late Professor Coats. Dr. J. Lindsay Steven moved "That the memorial take the form of a prize or scholarship to be called the Joseph Coats Memorial Prize in Pathology." Dr. David Newman, in seconding, said that £1,000 would be required for the foundation of a prize or scholarship. This having been adopted, the following were appointed a committee to carry out the scheme: The Principal (convener), Dr. H. C. Cameron (president of the faculty); Sir William Gairdner; the Professor of Pathology (if agreeable upon appointment); Dr. James Finlayson, Dr. J. Lindsay Steven, Dr. Donald Fraser (Paisley), and Dr. David Newman, secretary.

Newman, secretary.

Independently of the above subscriptions will be taken very soon among the students of the university for the purpose of erecting a "students' memorial" to the later professor. The form proposed is to be either a tablet in the pathology class-room or a bust on the grand staircase. Subscriptions will be limited to one shilling, and it is expected that the sum required will be raised independent of outside aid.

Will it come to anything? We ask the question-

Digitized by Google

advisedly in reference to the proposed memorial to the late Dr. Coats. Of course we do not in this question include the scheme of the students, for if unanimous, they will fulfil their intentions. Although we do not for a moment wish to put a wet blanket on the larger scheme, which we should like to see carried out, yet, when it is considered how many memorial schemes are at present before the Glasgow public, not one of which is as yet completed, we do not feel at all sanguine. Briefly, there is the Diamond Jubilee Memorial, for the purpose of raising funds for the rebuilding of the Glasgow Royal Infirmary. Certainly a large sum has been raised, but which is insufficient for the purpose. Then we have the private memorial for the late Principal Caird, and also the more public scheme for the arection of a stained-glass window in the Bute Hall.
3. The Lewis Carroll Memorial Cot Fund is not yet completed. 4. The memorial to the Brothers John and William Hunter. 5. Last week it was announced that a 4. The memorial to the Brothers John and great many citizens in Glasgow felt a great desire that they ought to hononr the late Mr. Gladstone with a statue, and to-day (February 15th) a meeting is to be held in the City Chambers for this purpose. Now we have the Joseph Coa's' Memorial Fund in hand. There can be no second opinion that the memoria ists are animated with the best intentions, but the public purse has limitations, and we have, nowadays, no ram's horns for the purpose of bringing down the walls, or of opening the pockets of the would-be benevolent; consequently these memorials have before now collapsed on account of their very frequency, and have been carefully put away until the next occasion for another memorial blast.

GLASGOW ROYAL INFIEMARY RE-CONSTRUCTION.—It is said that the plans for the reconstruction of the Royal Infirmary have now been revised and adjusted on the lines of the most recent suggestions of the staff, and it is expected that the Lord Provost's Committee will be able to announce without delay that the plans for the main or Cathedral Square elevation have been finally approved, so that no time may be lost in beginning the actual work of reconstruction. We hope when this takes place the public will come forward and subscribe the remaining £20,000, required for the completion of the object in view.

EXTENSION OF LEITH HOSPITAL.—In 1897 it was resolved to devote the local Jubilee Fund to increasing the number of the beds in Leith Hospital. Plans have now been drawn up and approved by the directors, acting in concert with the medical staff, which will increase the present hospital accommodation from 76 beds to 100. The previous enlargements of the hospital have always been of a more or less makeshift character, with the result that the administrative buildings, designed for a hospital of some fifty beds, have had undue stress thrown upon them. By the present scheme, however, a radical change will be be effected. What amounts to a practically new pavilion is to be erected, together with an entirely new administrative department. The total cost of the buildings, exclusive of furnishings and the value of the ground, works out at about £18,000. The sum contributed toward this by the Diamond Jubilee Fund is about £5,000, leaving the balance to be provided from the capital fund of the institution. It is hoped that the annual loss of income from the diminution of the capital fund will be more than compensated for by an increase in the ordinary income derived from subscriptions. That the hospital is economically managed is shown by the fact that the annual cost per bed is barely £50.

Manchester.

FROM OUR OWN CORRESPONDENT.

ROYAL INFIRMARY.—The annual meeting of trustees has just been held. Negotiations with the City Corporations respecting the future of the Institution are still proceeding. A clinical laboratory has been erected at a cost of over £400, and a curator is about to be appointed. During the year, 4,533 in-patients and 28,443 out and home patients received treatment. At

the Convalescent Home 1,717 cases had been dealt with. In connection with the Asylum at Cheadle, further accommodation is to be provided for epileptic cases. Two new posts are to be created, an aural surgeon and an additional assistant surgeon. Other changes in connection with the staff are expected during the coming year.

Tuberculosis.—Much local interest is being taken in the measures for preventing tuberculosis. The northwestern branch of the Incorporated Society of Medical Officers of Health has adopted a resolution approving of the compulsory notification of phthisis. The Consumption Hospital is making arrangements for carrying on the out-door treatment now so enthusiastically advocated.

INBRIETY.—The new Act is being ardently discussed, and a conference of representatives of local municipal corporations has just been held in Manchester. Statistics and estimates are to be immediately prepared in order to ascertain if the number of cases would justify the establishment of a reformatory on a sufficiently large scale.

lishment of a reformatory on a sufficiently large scale.

EXAMINATION OF MORBID PRODUCTS.—The Pathological and Medical Societies of Manchester have made arrangements with the authorities of Owen's College whereby their members may obtain investigation of preparations relating to tuberculosis, tumour formations, and blood diseases. The scheme has been in actual work for about six weeks, and promises to be of much value.

MEDICAL SOCIETY OF LONDON.

Last Monday's meeting was devoted to the exhibition of living specimens.

Mr. Watson Cheyne led the way with two cases of coxa vara after operation. His plan is to saw through the femur below the trochanters, and to invert the lower segment of bone maintaining the inversion by tacking a perforated plate of aluminium to the two ends of bone in the new position. The results in both instances were excellent, though in one an abscess had formed over the seat of the operation three years later, which when opened gave exit to the plate and tintacks. While he preferred this operation for young subjects, he thought that the alternative plan of sawing a wedge-shaped piece of bone from the neck of the femur might be preferable in adults.

Mr. Jackson Clarke referred to cases of his own in younger subjects in whom rickets was still active, which he had treated by the use of instruments designed to keep the foot looking forward, and to take the weight off the

hip. The results had been very saussaucty.

Dr. Maguire showed an interesting case of recovery after operation for cerebellar abscess in a young man; and Dr. St. Clair Thomson showed a case of what is usually described as Pharyngo-mycosis leptothrica, an affection of the tonsils which superficially resembles follicular tonsillitis, from which, however, it differs in every essential particular. In respect of the latter Dr. Hall pointed out that good results had followed the application of a 15 per cent. alcoholic solution of salicylic acid.

Dr. HECTOR MACKENZIE showed a man with an enormous thoracic aneurism, which extended from the clavicle above to the fifth rib below. In spite of its size the aneurism had given rise to very little inconvenience, and even now the man did not feel ill enough to go into hospital.

Dr. Mackenzie also showed a man who presented the characteriseic symptoms and signs of Graves' disease, of interest partly on account of his sex, and also by reason of the prominence of cutaneous itching, a symptom, he added, which was often complained of by patients suffering from myxedema while undergoing the thyroid treatment.

Mr. Chevre discussed the results of operation in these cases which, in his experience, had been uncertain. Dr. Maguier recognised cactus grandifolia in the treatment of the palpitation. Dr. Morison pointed out that these cases often improved of themselves by the efflux of time, and suggested that thyroid hypersecretion, if present, was probably only one manifestation of an essen

Digitized by Google

tially nervous disturbance. Dr. Hadiry observed that these cases often underwent spontaneous improvement, but some went into asylums, and others died either of the disease or of some intercurrent disorder.

In conclusion, Mr. Warren Low showed a man who, as the result of a fall, had sustained subcoracoid dislocation of the head of the humerus, with detachment and comminution of the great tuberosity and fracture of the glenoid fossa. They cut down and removed the head of the bone, as it could not, even when exposed, be returned to its normal position, and the man made a good

recovery with some movement of the joint.

Mr. Jackson Clarke related a similar case except that the tuberosity was not comminuted. He did not first open the capsule, and so did not know that the tuberosity was fractured, and it ultimately became necessary to remove first the head of the bone and then the limb, on account of the persistence of œdema.

THE PLAGUE IN INDIA.

THE latest news from Bombay as to the spread of the plague are to the effect that many fresh cases have appeared among the miners of the Kolar gold mining district. This outbreak has been followed by seven deaths. It is also reported that the disease shows a disposition to spread; if so, there will certainly be a stampede among the coolies, large numbers of whom are employed in the mines. Accordingly precautions have been taken to meet the danger, and the medical staff has been increased, while every effort is being made to induce the workpeople to submit to inoculation. From the perusal of carefully compiled statistics we gather that greater immunity from attack has been observed since Haffkine's newly-introduced serum has come into general use. The time required for securing immunity is much shorter in plague than in that of other infectious diseases. This averages from twelve to twenty-four hours, while in cholera it is four days; in vaccination against small-pox, seven days; in anthrax, twelve days; and in rabies, fifteen days.

In Dharwar town, the plague is rapidly on the decline, only one or two cases occurring daily, and consequently the alarm is gradually subsiding, and the inhabitants returning to their homes, which during their absence, have been thoroughly disinfected, and made habitable. Dharwar is the central headquarters of the collector and magistrate, as well as that of the Southern Mahratta Railway Company. Here, then, the plague inspectors took up their quarters, and established a hospital for the reception of the plague-stricken, with a fully equipped staff of medical officers, empowered to keep a close watch upon all travellers arriving and departing, all arrivals from infected districts, as Bangalore, Gadag, &c., being detained for twelve or twenty-four hours. These precautions have been found highly necessary; withal a lady from Bangalore was allowed to proceed direct to her residence in the Fort. On the second day after her arrival she was stricken with plague. She was without delay inoculated, and after the second injection the symptoms improved, and she made a good recovery. The inoculation results in Dharwar in the last week of December were as fol-

10W8		Present	Total attacks	Total deaths
		popula- tion.	from com- mencement.	from com- mencement.
Once inoculated	• • • •	2,610	115	42
Twice inoculated	• • •	6,906	29	7
Uninoculated	•••	1 866	1,172	916
Total		11 382	1 316	965

From this it will be seen that the twice inoculated secured almost perfect immunity from plague. The total number of persons inoculated up to date in the town of Dharwas was 17,076. Of these 8,844 were twice inoculated. In Belgaum, Hubli, and Madras the plague may be said to have quite disappeared. This result has been chiefly attained by the incessant and untiring care and atten-tion bestowed on all classes alike by the medical and sanitary officers appointed to the several plague stricken districts.

By a later mail we find that some considerable increase has taken place in the number of deaths from

plague in the city of Bombay. There were in the last week of January no less than 538 deaths reported, an increase of 80 over that of the previous week. In Mysore the disease is still following a fatal course, in spite of well considered precautionary measures in force with regard to the placing in quarantine all suspected persons travelling by railway. An infective native will contrive to slip through the meshes of the inspecting officer. A case in point is reported from Pretoria. The 'Indiana' case in point is reported from Pretoria. The Indiana steamship from Bombay landed a passenger suffering from suspected bubonic plague, and the infected person died next day at Middelbing. Plague is also spreading in Madagascar. In the town of Tamatava 285 cases have been reported with 195 deaths. Of the five Europeans infected one only died. The outbreak is chiefly confined to the present of t to the more populated towns, the whole of which are known to be in a sadly neglected filthy condition, sanitation in fact is almost unknown to the Malagasy, and its French occupation has tended to increase rather than diminish its malodours.

Obituary.

THOMAS COOKE, M.D. (PARIS), F.R.C.S., &c.

Many generations of medical students will learn with pain and regret of the sudden death of Mr. Thomas Cooke, the well-known anatomist and teacher of anatomy, of Brunswick Square, W., which took place without a moment's warning, while actually engaged in demonstrating to his class on Wednesday of last week. Mr. Cooke had been indisposed for some time previously, and had only returned from a rest at the seaside on the previous day, still unwell, but intent on resuming his work.

Mr. Cooke was the only son of Mr. John Hawley Cooke, and was born in America in 1841. He was brought up and educated in Paris where he graduated M.D. in 1870. He was interne at various Paris hospitals, and was also demonstrator of anatomy at the Ecole Pratique. He shared in the hardships of the siege of Paris, and this bitter experience was possibly not altogether foreign to his leaving that city and coming to London in 1870. In 1871 he married Comtesse Aglaë de Hamel, a lady of distinguished parentage, who, with several children, is left to mourn his loss.

Mr. Cooke took his M.R.C.S. in January, and his F.R.C.S. in June, 1871, and was forthwith appointed demonstrator of anatomy and physiology at the Westminster Hospital Medical School, where he vas subsequently appointed assistant surgeon, a post which he

held for many years.

In 1870, he founded the institution with which his name will remain associated, viz., the London School of Anatomy, Physiology, and Operative Surgery. Starting in a very small way, by his perseverance, energy, and untiring application to work, he ultimately built up a sort of extra-mural college which occupied an altogether unique position in the world of medical teaching. thoroughness of his methods and his conscientiousness in the training of his pupils gained the confidence of the authorities, and to this doubtless was due the fact that his was the only private medical school recognised by the London Colleges, the University of London, the Society of Apothecaries, &c.

Mr. Cooke was a teacher in the truest sense of the term. Teaching was, indeed, the aim and object of his existence. It was to him no mere livelihood: it was a sacrament. He toiled by voice and pen in furtherance of his object, which was to impress upon students and upon those who controlled their destinies the far reaching importance of practical work in the dissecting-room and in the laboratory. His indefatigable labours in this direction occupied most of his time, for he was little prone to amusements and his great distraction was writing appeals against the decay of practical anatomical study. He was the author of various works on anatomy, most of which are household words with students, especially those who had been unfortunate as candidates, and the names whereof it is therefore unnecessary to recapitulate here. The production of the final (eleventh) edition of his well-known "Tablets of Anatomy" occupied the last years of his life, and they were published but a few months since. He adhered to the original plan, but introduced copious illustrations, so that they constitute a compendium of anatomy complete in themselves.

During the last year or two Mr. Cooke undertook an active campaign against the existing tendency to drop dissectional anatomy in favour of what he contemptuously termed "scientific" anatomy, and there is no doubt that his protests were justified by recent tendencies. He published a number of appeals on this subject which are remarkable for their earnestness and evident fixity of purpose, and no one who has read these will deny that Mr. Cooke did good work in calling the attention of the

profession to this very important subject.

In his private life Mr Cooke was a man of sterling principle and earnest conviction, and if somewhat austere in demeanour there was an undercurrent of geniality which came to the surface on slight provocation. He was very popular with his pupils, who learned to respect in him the uncompromising disciplinarian associated with the ardent teacher. He possessed in a noteworthy degree the faculty of securing the attention of his classes, and this, in the absence of the means at the disposal of most lecturers, seeing that his pupils were all voluntary. Mr. Cooke represented, in his person, probably the last of a long and distinguished series of teachers of anatomy working outside academical lines, and his success as a teacher made his school the foremost of its kind in this country. He died on his field of battle—the dissecting room - and it would be difficult to imagine a more appropriate ending for a life largely spent therein either as student or teacher.

Correspondence,

We do not hold ourselves responsible for the opinions of our

AN EXPLANATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

Sir, - In your report of the proceedings at the Edinburgh Medico-Chirurgical Society's meeting last week, your reporter appears to have quite misunderstood my remarks. What I did say was that Kanthack, from consideration of the organisms from the case of Ozena, had surmised that in cases of Cancrum Oris there would be probably found, as cause, the diphtheria bacillus, or at all events, a debased form of it, and that had prepared me for what I did find. Both in the case of Cancrum Oris and in the case of slow (not acute) spreading gan-grene, with slough formation, I found a similar bacillus, resembling in 24 hours culture, the diphtheria bacillus of 48 hours, and longer, cultures, when it shows involution forms. In several ways it, however, differed from the diphtheria bacillus. The other case was not a case of phagedenatous chancre; in fact, I stated that venereal possibilities had been absolutely excluded. Moreover, it was Dr. Muir who separated a somewhat similar organism in that case, not myself.

Finally, subcultures only approximated slightly to the form of the diphtheria bacillus. There was still clubbing of the ends of the organism which remains even after six

subcultures.

I am, Sir, yours truly,

Edinburgh, February 10th, 1899. T. SHENNAN.

EXPECTATION OF LIFE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR.—There is another method of calculation in use. I believe, among actuaries which varies somewhat from that you mention, and gives a little longer expectancy. It is to add to the actual age of the individual two-thirds of the difference between it and 80, a limit of life which is certainly more reasonable than that of 86.

Thus: deduct present age, 42 from 80, result 38; add two-thirds of this number, 25; the net result is the probable duration of life—67 years. By your

method it is 64 years.

I am, Sir, yours truly, L. B.

To the Editor of THE MEDICAL PRESS AND CIRCULAR SIR,—I desire to bring to the notice of the profession a new form of drainage-tubing—practically self-retaining, and which I have found to answer admirably.

NEW SELF-RETAINING DRAINAGE TUBING.

It consists of ordinary drainage tubing of various sizes perforated along its entire length at intervals of about three-quarters of an inch, and between each perforation,

on either side of the tube, are studs, or wings, which being of the same elastic material as the tube and cast together in one mould, offer no resistance during the process of introduction, and, as the drainage tissues close around the tube, these stude offer points of resistance and effectually prevent its slipping out. My suggestion has been very well carried out by Messrs. Arnold and Sons, of West Smithfield, with their usual care.

I am, Sir, yours truly, T. CARTER WIGG, M.D., M.R.C.S., &c.

Literature.

THE SYDENHAM SOCIETY'S LEXICON. (a)

WE learn from the Report of the Society that "It is confidently hoped that the Lexicon of Medical Terms may be completed within twelve months. Considerable progress has been made in the preparation of a Supplement, which will follow the completion of the main work." We congratulate the editor on the industry that made the notice in the Report possible; and we congratulate the notice in the resport possible; and we congratuate the profession on the possession of the best technical lexicon ever produced. Every page bears evidence of ripe scholarship and increasing vigilance.

In 1878 the first number of the Lexicon was issued.

and year after year with unfailing regularity number followed number. Few subscribers think of the great labour entailed in producing a number, and some time since we took the trouble to find the average number of pages and words in each. We find the pages number 160, double columned, containing in all, 9,600 words.

If any reader cares to trace the origin of a word, to give a definition of it, to find the effect of time on its meaning, and to mark its increased or lessened use, he may form some idea of so treating 9,600 words a year. Then, and then only, can a true value be placed on this magnificent work which the New Sydenham Society has given to its subscribers.

Parliamentary Aews.

VACCINATION: CERTIFICATES OF EXEMPTION.

In reply to Mr. Johnson-Ferguson, the Home Secretary said he had no power to enforce uniformity in respect of the fees charged for certificates of exemption from vaccination, though in the model table of fees drawn up in his office for the guidance of local authorities he had inserted a small inclusive charge for these certificates. In respect of the requirement by some magistrates of the production of the birth certificates of the children for whom exemption was demanded, he said he was advised that this was within their discretion.

UNVACCINATED CHILDREN.

In answer to a question put by Mr. BARTLEY, the President of the Local Government Board observed that there were no returns or other source of information to justify the assumption that the number of children not protected by vaccination was largely increasing. He pointed out that since 1885 the total number of children

(a) "The New Sydenham Society's Lexicon of Medicine and the Allied Sciences." (Based on Mayne's Lexicon.) Twenty fourth Part. Scap. Tape. London: The New Sydenham Society. 1898.

remaining unvaccinated had steadily increased year by year, from 136,000 in 1885 to 370,000 in 1898, the total number for the whole period being 3,235,000. Of these, certificates of exemption were given in respect of only 289,000. Since the new Act came into full operation the demand for glycerinated lymph had been so great as to render necessary a large increase in the staff engaged in its production and distribution, a fact from which he drew a favourable inference. On the whole, as the Act had only come into full operation six weeks ago, he was not in possession of sufficient information as to its working to justify his making any proposal for a modification of the Vaccination Law.

THE PURITY OF MILK.

In answer to a question put by Mr. Channing, the the President of the Local Gevernment Board, stated that the Government had arrived at a decision as to the portions of the recommendations of the Royal Commission on Tuberculosis, to which effect ought and would be given, but he questioned the necessity for a General Bill having for object to secure better protection to con-sumers from tuberculous infection of milk. He announced the forthcoming issue of an Order extending the definition of "disease" in the Dairies, Cowsheds, and Milkshops Order of 1885, so as to include in the case of a cow such disease of the udder as shall be certified by a veterinary surgeon to be tuberculous. He also announced that he was about to issue a circular to local authorities dealing with various other matters comprised in the report of the Commission. In answer to a further question, Mr. Chaplin added that he had considered the possibility of tuberculosis being introduced by foreign milk.

COMPULSORY VACCINATION IN THE SERVICES.

In reply to a question put by Mr. BARTLEY, Sir J. Gorst stated that Art. 35 of the Education Code, requiring candidates for pupil-teacherships to be vaccinated, was still being acted upon.

In reply to further questions by this gentleman, it was stated that no man is enlisted unless he consents to be vaccinated, and that vaccination is enforced on all men and boys entering the Navy.

DEPRIVATION OF MEDICAL DIPLOMAS FOR ERIMINAL CONDUCT.

THE attempt of the Parliamentary Bills Committee of the British Medical Association to obtain an amendment of the Medical Act which would deprive any practitioner convicted of criminal conduct of his diploma and degrees, and of his qualification to practise, has met with an un-expected opposition. The Council of the Royal College of Physicians of London declares that the particular clause of the amending Bill would infringe its privileges. Great efforts are being made to induce the College to withdraw its opposition, and the contention is made that the proposal is in harmony with the general views of the profession. At the present time a criminal practi-tioner may be struck off the register, but still retain his diploma and qualification. A conciliatory conference, to be attended by members of the Bills Committee and of the Council of the College, has been suggested.

Medical Rews.

The City of London Lunatic Asylum

THE Corporation of London have decided to make improvements at the City of London Lunatic Asylum, at Stone, near Dartford, at a cost of £85,850. The original estimate—£70,000—which the Common Council accepted in October, 1897, included £12,095 for the warming, heating, lighting, and engineering works in connection with the new building, but further inquiry has led to the condemnation of existing boilers, which have been in use since 1865, and to the introduction of an entirely new system. This, together with the installation of the electric light in the asylum, has necessitated an increase in the expressed fels for him or the electric light in the asylum, has necessitated an increase in the expenses of £15,850, bringing the total to £85,850. A Report sanctioning that enhancement passed the Corporation last week.

Medical Aid Association and the M.D.U.

THE MEDICAL PRESS.

THE following motion will be discussed at the meeting of the Medical Defence Union, which takes place tomorrow (Thursday):- "Inasmuch as medical aid associations adopt measures which are highly objectionable in character, and are subversive of the best interests of the profession, the council of the Medical Defence Union strongly recommend the members of the Union at the next annual meeting to pass a resolution authorising the council to decline to accept as members gentlemen holding office in such associations.'

The Dubl n Hospi'al Sunday.

THE Council of the Fund will meet at the Shelbourne Hotel, Dublin, on the 16th inst., to receive the reports of the executive committee with regard to collections, visitation of hospitals, and other matters.

Coming Congresses.

- THE following Congresses are announced:—1. German Surgical Society, Berlin, April 5th. President, Professor Hahn.
- 2. Portuguese Congress of Medicine, in Oporto, in
- 3. On Prophylaxis of Syphilis and other Venereal Diseases, at Brussels, September 1899.
 4. Balneological Congress, at Berlin, March 3rd, 1899.

The Weber-Parke: Prizes.

THE Royal College of Physicians of London has announced that, in 1900, it will award the prize of £150 and two silver medals for the best essay on the Etiology of Human Tuberculosis.

The Irish Union Drug Contract System.

It having been reported to the Guardians of the South Dublin Union by Sir Charles Cameron that the linseed meal supplied by Leslie and Company, the contractors, was nothing but ground cake, a prosecution of the firm was ordered. They wriggled out of the difficulty by pleading that the contract was taken before the issue of the new Pharmacopœia, and that they were not bound to the standard of that book.

Epidemic at Peterborough.

An epidemic of a rather obscure disease is prevalent among the young in one of the suburbs of Peterborough. It presents some resemblance to scarlet fever, and is very infectious. Several deaths have occurred, and the schools have been closed for the present.

Mortality among American Troops in the Philippines.

The death roll among the American soldiers at the Philippines amounts to 220, including 40 from wounds and accidents, 65 from typhoid fever, 43 from small-pox, and 22 from dysentery. Vigorous measures have been taken to prevent the further spread of small-pox, and twelve medical officers have been told off for the express purpose of vaccinating the natives.

A New Hospital Gaze te.

Not to be behind the times the Westminster Hospital Medical School is to the fore with a gazette of its own, of which the first number is now before us. The page facing the first page of text is graced with a very smart sketch which we take to represent Mr. Stonham whose good natured, though somewhat cynical, physiognomy is very cleverly delineated by the hand of an anonymous artist. This first number does credit to its editors, and if they can maintain the standard of witful waggishnsss no old student of the school will willingly deprive himself of the pleasure of revisiting mentally the scenes of his early years. There is nothing like a gazette to maintain intact the bonds which should unite all students of a nedical school. But too often they lose touch of each other and of the school, and forfeit that esprit de corps which is indispensable to continuity of tradition.

Salary of Irish Poor-law Dispensers.

THE Irish Local Government Board has refused to sanction a salary of more than £15 a year for the dispenser of the Skibbereen Union.

PSITTACOSIS, the infectious pneumonia spread by parrots, has broken out again in a number of Italian towns. Some years ago it prevailed extensively in Genoa and Florence, but a municipal decree forbidding the keeping of parrots in private houses put an end to the epidemic.

Aotices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CANDOUR.

The Yorkshire Post publishes the following advertisement:—
"Wanted.—Young man as Dispenser, knowledge of dispersing not necessary. Address, stating salary expected. &c., &c."

not necessary. Address, stating salary expected. &c., &c.'
MILO—London can no longer lay claim to being the healthiest
of European cities. Ten yeas a sago the death rate was 19°9, and in
1898 it was 17°2. During this period the death rate of Rome, which
ten years ago stood at 22°6, has been reduced to 16°9, and that of
Berlin has fallen from 20 4 to 17°7. Amsterdam has the lowest
record of any, having in ten years fallen from 20°2 to 15°8. Ten
years ago Stockholm had the same death rate as London, but
instead of a reduction of 1 per 1 000, there is an improvement to the
extent of 3 per 1,000, and to-day the figures stand at 16°7. Busselhas fallen from 20°2 to 16°6, and Copenhagen from 20°5 to 17°5 in
the same period. the same period.

DR. GEORGE FLEMING. - Our best thanks are tendered to our correspondent for the very valuable information vouchsafed, on the use of tuberculin as a means of discovering the existence of tuberculosis in suspected cattle.

PHYSIOGENIC CATHARSIS.

(A reply on the most recent model.)

IGNORANUS.—Your letter received. We consulted our distinguished friend, Professor Dry-as-Dust Vole, on the question. He considers that the brisk cathartic effect was probably due to the medicine you prescribed, viz. A bolus of ten grains of calomel, with sixty grains of the compound powder of jalap, taken at bedtime, and followed by two ounces of black draught the following morning. The learned Professor writes that after much research, he concludes that the bolus and draught were sufficient to account for the symptoms described.

MR S. P.—MS. received. and will be utilized.

MR S. P.-MS. received, and will be utilised in an early number.

B. L.—Should have sent his communication to the office in the division in which he resides. It would have saved time.

SURGEON-GENERAL FRANCIS' paper is marked for insertion in

OUT COL.

P. D. (South Coast).—In view of the fact that a new water supply is being sought by your district, the question you ask is to the point. The answer has often been insisted upon in the columns of the Medical Press and Circular, namely, that no water that has once been polluted by sewage can be regarded as a satisfactory source of public supply. That view has been abundantly supported by recent bacteriological advances, and by the experiences both of our own and of foreign countries. In any case our correspondent may protect himself by boiling the water before using it for drinking purposes, or he may sterilise it by passing it through a Pasteur filter, or the Berkfeld filter, both of which act on the principle of freing the fluid through glazed porcelain. The elementary facts about wholesome and unwholesome water might well enter into a Board school education, and would replace with advantage some of the fanciful ubjects now taught.

Dr. Herrifs. - We much question whether the scheme will ever prove successful, and before becoming a subscribing member we think that our correspondent had better wait a little.

Meetings of the Societies and Lectures.

WEDNESDAY, FEBRUARY 15TH.

ROYAL MICROSCOPICAL SOCIETY (20. Hanover Square, W.)—7.30 p.m. Mr. J Rheinberg: Exhibition of Objects shown by Multiple Colour Illumination. 8 p.m. Meeting.
NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospita).—8,30 p.m. Dis ussion on the Relation of Gout to Rheumatoid Arthritis. (Opened by Dr. W. Ewart.)

THURSDAY, FEBRUARY 16TH.

HARVRIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road).—9.30 p.m. Dr. A. Whitfield: Varieties of Eczema and their Treatment.

Vacancies.

Colonial Office, London.—Medical Officers for temporary service on the Gold Coast, for one year. Unmarried. Salary at the

rate of £350 a year, with quarters, or an allowance in Herrice thereof. Also Medical Officers for the West African Frontier. Force on the Niger. Apply personally to the Assistant Private Secretary at the Colonial Office, Westminster.

County of Lanark.—Assistant Medical Officer of Health. Ralary, commencing at £130 per snuum. Applications to Dr. Wilson, County Medical Officer, Hamilton, N.R.

Dalrymple Home for Inebriates, Rickmansworth.—Resident Medical Superintendent, married. Salary £200 per annum, unfurnished house, food, coals, gas, &c., provided.

Hereford General Infirmary.—Assistant House Surgeon and Dispenser for two years; unmarried. Salary £75 per annum, with board, residence, and washing.

Hertfordehire Cunty Asylum, Hill End, St. Albans —Assistant Medical Officer, unmarried. Salary commencing at £130 per annum, with fu nished quarters, board, washing, and attendance.

annum, with lubished quarters, board, washing, and attendance.

Kent C unty Luna'id Asylum Barming Heath, near Maidstone.—
Fourth Assistant Medical Officer and sathologist. Ralary commencing at £175 per annum, with residence, attendance, coal, gas, and washing. Applications to the Superintendant, Barming Heath Asylum, Maidstone.

Liverpool School of Tropical Diseas s.—Lecturer in Tropical Diseases. Salary £250 asyar and proportion of students' fees, with the right of private practice. Applications to Professor Boyce, University College, liverpool.

Norfolk and Norwich Hospital, Norwich.—House Surgeon for two years. Falary £30 per annum, with board, lodging, and washing.

University College. Sheffield.—Demonstrator in the Bacteriological Laboratory. Salary £150.

Liversity of Glasgow—Chair of Pathology. The normal salary of the Chair is fixed by Ordinance at £1,100 For particulars as to applications, see advertisement in another column.

Appointments.

ANNETT, H. E., M.B., Ch.B.Vict., D.P.H., has been appointed Demonstrator of Tropical Pathology in the newly-founded School of Tropical Diseases in Liverpool.

BYERS, PROF, J. W., M.A., M.D., M.A.O. (Hon. Causa), Examiner in Midwifer 7 to the Royal University of Ireland.

KEVIN, BYENE P., M.D., B.A., B.A., Medical Officer to the Christ Church District of the Parish of St. Marylebone, Lendon.

LEY, J. W., F.B.C.S. Eng., Medical Officer for the Newton Abbot Cottage Hospital, District and Workhouse.

MAYSTON, R., W., M.B.Lout., M.R.C., Bug., L.R.C.P. Lond., House-Physician to the Seamen's Hospital, Greenwich.

Births.

OSBORN.—On Feb. 7th, at the Chalet, Dover, the wife of Arthur Osborn, M.R.C.S., and L.R.C.P., of a daughter.

SAYRES.—On Feb. 12th, at Woodford, Essex, the wife of A. W. F. Sayers, M.D., of a son.

Marriages.

Bowss-Lee.- On, Jan. 9th, at Christ Church, Herne Bay, Tom-Armstrong Bowes, M.D., third son of John Bowes, M.E.C.N., of Herne Bay, to Gettude Anne, youngest daughter of George Lee, Victoria Park Road, Herne Bay.

Cocking-Birks.—On Feb. 9th, at the Pari-h Church, Sheffield, Wm. Tusting Cocking, M.D.Lond., to Alice Mary, youngest daughter of Edward Birks, Birchcliffe, Broomhali Park, Sheffield.

Park, Shemeid.

Darling-Smaill.—On Feb. 8th, at ft. John's Free Church, Edinburgh, Thomas Brown Darling, M.D., of Merchiston Place, Edinburgh, to Elizabeth Lumlop, second surviving daughter of the late George Barclay, and widow of W. R. Smaill, Edinburgh.

Smaill, Edinburgh.

HUDSON—KEMPTHORNE BENNETT.—Feb. 8th, at Wynberg, Capetown, Ainslie Hudson, M.D., F.R.C.S. Edin., of East London, Cape Colony, only son of the late Rev Charles Hudson, vicar of skillington, Lincs, to Bertha, only child of Mr. G. C. Kempthorne-Bennett, of Maldeira, Wynberg.

WOODYATT—ROWGEFT.—On Feb. 9th, at 8t. John's Church, Ca'erham Valley, John F Woodyatt, M.R.C.S., L.R.C.P., of Halifax, Yorkshire, to Violet Isab I youngest daughter of Major-General G. C. Rowcroft, J.S.C., of Hampden Mount, Caterham Valley,

Deaths.

DEE.—On Feb. 8th, at his residence, 40, Brunswick Square, London, suddenly, Thomas Cooke, M.D., F. M.R.C.S. (Kng.), aged 57.
11.—On Feb. 4th, at Albion Street, Lewes, Frank Algernen

Aged 57.

HAIL.—On Feb. 4th at Albion Strett, Lewes, Frank Augusta Hall, M.R.C.S., in his 52nd year.

MACAULAY.—On Feb 4th at Ashfield, Halifax, Madge, the dearly beloved wife of D. J. Macaulay, M. D. Brux., L.R.O.P., J.R.C.S. Edin., L.F.P.S. Glasg.

MACDOUGALL.—On Feb. 9th, at Dunollie, Oban, Henry R. L. MacDougall, of MacDougall, Deputy Surgeon General, late Bombay Army, aged 63.

MORRISON.—On Feb. 1st, at 8t. Mary's Hospital, London, Henry Morrison, Surgeon, of Hounslow, Middlesex, aged 78.

WALKER.—On Feb. 1st, at Newton Heath, Mancrester, Alexander Walker, M.D., sged 49 1 cars.

'SAXIN'

Has been aptly termed the "Sweetest thing on earth." It is about 600 times sweeter than sugar and more delicate in flavour. 'Saxin' undergoes no change in the system, and may be safely prescribed in all cases where sugar is harmful.

'8axin,' 1/4 gr., is supplied in bottles of 100 and 200, at 7d. and 1s. 1d. per bottle.

'EMOL-KELEET'

Is a natural powder, containing a large proportion of native silicates. It has proved successful for drying weeping surfaces when all other powders have failed. Its soft, silky texture, soothing influence and other physical qualities enhance its healing action.

'Emoi-Keleet' is supplied in neat metal boxes, at 9d. per box.

Burroughs Wellcome and Co., London and Sydney.

LISTERINE.

THE STANDARD ANTISEPTIC.

- LISTERINE is a non-toxic, non-irritating and non-escharotic antiseptic, composed of ozoniferous essences, vegetable antiseptics and benzo-boracic acid.
- LISTERINE is sufficiently powerful to make and maintain surgical cleanliness in the antiseptic and prophylactic treatment and care of all parts of the human body.
- LISTERINE has ever proven a thoroughly trustworthy antiseptic dressing for operative or accidental wounds.
- LISTERINE is invaluable in obstetrics and gynecology as a general cleansing prophylactic, or antiseptic agent, and is an effective remedy in the treatment of catarrhal conditions of every locality.
- LISTERINE is useful in the treatment of the infectious maladies which are attended by inflammation of accessible surfaces—as diphtheria, scarlet fever and pertussis.
- LISTERINE diluted with water or glycerine speedily relieves certain fermentative forms of indigestion.
- LISTERINE is indispensable for the preservation of the teeth, and for maintaining the mucous membrane of the mouth in a healthy condition.
- LISTERINE employed in the sick-room by means of a spray, or saturated clothshung about, is actively ozonifying and rapidly oxidizing in its effects upon organic matter afloat in the atmosphere.
- LISTERINE is of accurately determined and uniform antiseptic power, and of positive originality.
- LISTERINE is kept in stock by all worthy pharmacists everywhere.

The Barben Lectures.

THE ADMINISTRATIVE CONTROL OF TUBERCULOSIS. (a)

By SIR RICHARD THORNE THORNE, K.C.B., M.B., F.R.S.,

Medical Officer of the Local Government Board.

LECTURE I.

I DESIRE in the course of these lectures to consider how far it is practicable to control and prevent tuberculosis in the human subject by means of administrative measures. With that which merely happens to fall within the range of possibility, but which is obviously not within the range of practice, I do not intend to concern myself at any length. I may, however, at times find it necessary incidentally to refer to measures which, though excellent in theory, must, in my opinion, be set aside as incapable of application.

As a preliminary to the discussion of this subject, it becomes necessary to ascertain, as far as we can, what is the extent and character of the evil that has to be contended with; and this inquiry leads us, in the first instance, to consider how far this point may be elucidated by the aid of vital statistics. Hitherto, the statistical aspect of the question has been very involved and obscure, but the data supplied by Dr. Tatham to the Royal Commission on Tuberculosis, 1896, have made this part of my task distinctly easier, and I do not hesitate to make considerable use both of his evidence and of the tables which he submitted to that Commission.

It is well known that before 1874 the medical certification of causes of death was optional, and that for a long period antecedent to and for some time subsequent to that date, even those deaths which were classed as certified can by no means be so regarded from the medical point of view. It is also matter of notoriety that a number of deaths now referred to tuberculosis were formerly not so referred; whereas, on the other hand, many deaths formerly certified as due to one or other form of tuberculosis are now differently classified. Owing to these causes it is not possible to make any exact comparison between the rates of death from tuberculosis as a whole, and from the different forms of tuberculosis, at different periods of time since the passing of the Act for the Civil Registration of Deaths in 1837, or even since 1847, when, for the first time, the causes of death in combination with ages were abstracted in the General Register Office of England and Wales. But it is a matter of satisfaction to have the official assurance of Dr. Tatham to the effect that even for this purpose the available statistics are not without value.

Taking deaths registered from "All Forms of Tuberculous Disease," first in the three decennial periods 1851—1860, 1861—1870, and 1871—1880, and then in the quinquennial periods 1881—1885, 1886—1890, and 1891—1895 in both sexes and at all ages, it appears that the rate of death per million living has undergone continuous diminution, and that whereas the rate for 1851—1860 was 3,483, it was only 2,122, which exhibits a diminution of 39 1 per cent. in 1891—1895. And further, when these two groups of years are compared for each separate age-period for which the material is available, it is found

that the rate for 1891—1895 invariably exhibits a marked reduction as contrasted with that for 1851—1860. Indeed, with but few exceptions, the reduction shows itself to have been continuous for each period referred to throughout the term of forty-five years in question.

This cannot but be matter of satisfaction; and that satisfaction is enhanced, in so far as purposes of State are concerned, when it is noted that by far the greatest amount of reduction in death from tuberculous disease sets in during the period of incipient youth, reaches its maximum in the period of full adolescence when human life is commonly at its highest value to the nation, and that it still obtains throughout the period of adult man-hood and womanhood. Although, therefore, it remains true that we are dealing with a group of diseases which is still so fatal as to cause some 60,000 deaths annually in England and Wales, yet it ought not to be forgotten that for a long series of years we have been steadily advancing in the adoption of measures tending to diminish preventable disease, and that, speaking of death from tuberculous diseases as a whole, we have no cause to be ashamed of the result achieved. But when we come to examine all the available statistical records in detail we find that this reduction has not been uniform, either as regards the different forms of tuberculous disease or as regards persons living at different ageperiods.

Thus, when we look at the rates of mortality from "Phthisis," we find that in each of the five-year periods up to 25 years of age there have been reductions which are distinctly in excess of those affecting the same age-periods from "All Forms of Tuberculous Disease"; indeed, it seems clear that much of the reduction referred to under the latter heading has been due to a fall in the phthisis rate. The reductions in the rates of death from phthisis at the earlier age-periods are doubtless vitiated by reason of improved diagnosis and improved certification in the later as contrasted with the earlier periods; but there remains the fact that there has been reduction at every age-period, and also that in the several age-groups included in the age-period 15—45 years, when the mortality from phthisis is still very heavy, the contrast between the rates in 1891—1895 as compared with 1851—1860 shows for the later of the two periods reductions ranging from no less than 32 to 58 per cent.

So, also, there are phases in the statistical history of fatal tuberculosis in England and Wales which, instead of affording ground for satisfaction, lead us to inquire how it is that amidst the general saving of life from tuberculous disease which has been at work, we have so signally failed to secure its benefits to a large class of the most helpless of the population, namely, infants and young children who are still claimed in almost undiminished and even increasing numbers as victims of "Tabes Mesenterica," a term the use of which is mainly limited to disease and death occurring in infancy and childhood. Taking the rate of mortality under this heading per million living at all ages, there has been a diminution from 260 in 1851—1860 to 238 in 1891—1895, namely, one of 8.5 per cent. But under one year of age the corresponding rates were 3,169 for 1851—1860 and 4,046 for 1891—1895, mamely, an increase of no less than 27.7 per cent.; and during the period under 5 years there was only a trivial decrease at the rate of 3.0 per cent. These rates stand in striking contrast with those for "All Forms of Tuberculous Disease," and still more so with those from "Phthisis."

Thus, when we compare the vital statistics as to tuberculosis in this country during the early and the later

⁽a) Abstract of Lecture I, on "The Administrative Control of Tuberculosis."

years of a period which well-nigh covers the last halfcentury, we find as follows:-

(1) There has taken place a remarkable reduction in the rate of death from "All Forms of Tuberculous Disease," this reduction being most marked during the age-period 10-35 years.

(2) There has been a still more remarkable reduction in the rate of death from "Phthisis," this reduction having been greatest at the several age-periods ranging

from infancy up to 35 years.

(3) Notwithstanding the fact that at the earlier periods of life there have been reductions in the rate of mortality from the two groups of tuberculous disease referred to, there has, on the contrary, been a large increase in the rate of death from "Tabes Mesenterica" under one year of age, and such reduction in the rate of death from this cause, as has taken place during the first five years of life, has been altogether insignificant.

When, therefore, we come to discuss the question of the administrative measures which may tend to the prevention of tuberculous disease in this country, it behoves us to seek some explanation of these conflicting results, which are the outcome of the past, and to ask ourselves the question Can a reason be assigned for the fact that whilst signal success has been obtained as regards reduction in the death-rate from the two groups of tuberculous disease first named, there has been almost entire failure, and at one age-period worse than failure, as regards the third form referred to? No sufficient answer can be given to this question until we have sought to learn, in the first instance, what have been the influences—administrative and other—which have been at work in our midst during the period governed by the statistics quoted, and which at one and another period of life have gone to modify, for better or for worse, the death-rate from one or another form of tuberculosis.

Among the influences that have been at work in the past I have no hesitation in assigning a foremost place to those administrative measures which have gone so far to secure for men, women, and children the benefits of free movement of air and free access of sunlight as regards both their dwellings and their places of labour. When we recall the descriptions given between twentyfive and fifty years ago as to the overcrowding of houses on space, and of people within the houses in some of our large towns and cities, and as to the incidental evils, both physical and moral, which always go hand in hand with that obvious breach of Nature's simplest law, by which our fellow subjects are deprived of air and light, and then compare the existing state of affairs in those same cities, we may be proud of the achievements of the past half-century, even though we may deplore that the change has not been so complete as we could have

There is abundant evidence of the advantages brought about by metropolitan improvements; and the wellknown investigations of Dr. Tatham in Salford have afforded definite proof of the value of this open space in the reduction of that form of tuberculosis in which the infection is mainly conveyed through the air. Thus, in districts where all the houses were built on the vicious system known as "back-to-back," the phthisis death-rate was 5.2 per 1,000 living; where 56 per cent. of the houses were so built the rate was 3.6; where 23 per cent. only were so constructed it was further reduced to 3.3 per cent.; and, lastly, where there were no "back-to-back" houses, that is to say where all houses were provided with some means of light and air both in front and to the rear, the rate was only 2.8. The result is also the more remarkable because, as Dr. Tatham puts it, "with the exception of the means for through ventilation, the back-to-back houses as a whole are in a better sanitary state than the through-houses.'

Modern research has supplied the explanation of this, for we now know that there are few things more destructive to the bacillus of tuberculosis than exposure to the combined influence of sunlight, or even ordinary day-light, and of movement of air. Such research affords also an incentive to further progress in this matter, but I cannot help calling attention to the fact that the great progress in this country in the reduction of the phthisis death-rate was in full operation before the discovery of

the tubercle bacillus, and before any action could bebased on the knowledge since acquired, to the effect that we had to deal with a living infective organism.

Administrative measures, including the adoption of bye-laws as to new dwellings, have also gone to secure much greater dryness of the sites of dwellings than formerly obtained. I refer to the draining of the subsoil, to the concreting of the ground surface of dwellings, to the provision of damp courses in walls, to the proper collection and disposal of rain falling upon roofs, and to the paving of yards. It is certain that the reduction in the rate of death from phthisis has gone hand in hand with a reduction in soil wetness; and here again we have an indication as to one of the lines of further administrative action in so far as the surroundings of our towns,

villages, and dwellings are concerned. The influences I refer to, and many others due to administrative action of one and another sort, must, however have operated on persons at all ages; indeed, this is shown in the table dealing with "All Forms of Tubercu-losis" and in that relating to "Phthisis," where it will be seen that the important reductions effected apply to infancy and childhood as well as to adolescence and mature age. Hence I am unable to find in these influences any sufficient answer to the question, Why has there been failure, and even worse than failure, to diminish the toll of death paid by our infant population from that form of tuberculosis which is registered under the name of tabes mesenterica? When, however, we remember that in the case of phthisis or pulmonary tuberculosis the tuberculous infection is mainly received aerially, whereas in the case of tabes mesenterica it is mainly received by the digestive tract, we get an indi-cation which tends to solve the difficulty. The varicus cation which tends to solve the difficulty. The varicus administrative measures to which I have thus far adverted have, in so far as tuberculosis is concerned, tended in the main to diminish the chances of the aerial diffusion of the tuberculous infection. They have also tended to prevent those forms of pulmonary mischief which must necessarily facilitate the retention in the tubercle bacillus of its vitality and its power of reproduction when once this pathogenic organism is received into the lungs. Is it possible that during the period in which there has been so vast a saving of human life from that form of tuberculous disease, namely, phthisis, in which the infection is conveyed aerially, there have been in operation one or more influences under which the tuberculous infection has had such increasing facilities for reaching the digestive tract as to have altogether outweighed, at least among our infant population, the benefits which would otherwise have followed a controlling action of the sort to which I have referred? I believe there have; and this leads me to consider how that infection may reach the digestive tract.

Two of the conclusions of the Royal Commission of 1890, will suffice to justify the prominence which is here given to the question of food supplies in relation to human tuberculosis. One runs as follows:—"Any person who takes tuberculous matter into the body as food incurs risk of acquiring tuberculous disease." The other incurs risk of acquiring tuberculous disease." The other is:—"No doubt the largest part of the tuberculosis which man obtains through his food is by the means of milk containing tuberculous matter." Taking these conclusions as a sort of text, I am driven at once to divide my subject into two parts. One deals with the influence of meat, the other with that of milk, in the production of human tuberculosis.

Meat. The demands for the adoption of administrative measures in order to control the risk to man of acquiring tuberculosis through the agency of meat have mainly come from certain medical officers of health having experience of public slaughter-houses and from those who are engaged in the meat trade. The former have largely based their demands on physiological considerations; the latter, who naturally view the matter from a commercial point of view, have in the main enforced their requests by referring to seizures of carcases and by quotations from the report of the Royal Commissson appointed in 1890.

In considering these demands I would note that they have, in the main, had concern with the meat derived from bovine animals. This has distinct interest for us,

because whatever the influence of race may be on the occurrence of tuberculosis in the lower animals, it is certain that animals of the bovine race lead a much more unnatural life in this country than do sheep, for example, among which latter animals tuberculosis is comparatively rare. Indeed, next to the milch cow, and perhaps the pig, there is probably no animal, the flesh of which is used as a food for man, so liable to tuberculosis as the well-stalled bullock. In support of the contention that this contrast between bovine and ovine animals is not exclusively an affair of race, I would recall a piece of personal experience. When visiting the public slaughterhouses of one of our large cities I was shown, as a curiosity, a group of cows. To me each cow seemed to consist of little more than a skeleton framework covered tightly with a hide, and in my ignorance I asked if the lot had been condemned, even before slaughter, as unfit for human food. To my astonishment I was informed not only that this was not so, but that cows of the same class were often received from the same locality, and that they were peculiar inasmuch as tuberculosis was very rare among them. They were disused milch cows from some of the poorest of small tenant farmers in the United Kingdom. Although they had been milked as long as it was practicable to milk them, they had mainly subsisted on such grass as they could pick up, and their former owners had been unable to provide for their protection in stalls against inclement weather. In short, though in one sense their life had been a hard one, they had enjoyed the benefit-inestimable from the point of view of tuberculosis-of having lived in the open air.

But tuberculosis in animals, the flesh of which is used for human food, notably in those of the bovine race and in the pig, is a reality; and in considering how far it may be controlled by administrative measures, it will be well to ascertain, as far as this is practicable, what evidence is available as to the extent of the mischief induced by the use, as food, of the meat of tuberculous

animals.

With such evidence before me I fully admit that there are conditions under which tuberculous disease can be and is communicated to man as the result of the use, as a food, of the meat of tuberculous animals, but I fail to find any evidence justifying the view that the disease is so communicated to any wide extent. To the limited extent to which vital statistics enable us to form a judgment, the conclusion would be in the opposite direction

Such positive results as were obtained by certain experiments carried out by the Royal Commission of 1890 were achieved under altogether exceptional circumstances. They serve indeed to represent a risk, and even an occasional danger; but it is not one, in my opinion, that justifies some of the claims that have been based upon it. It should also be remembered that the Royal Commission of 1890, having these facts before them, reported that "tuberculous matter is but seldom found in the meat substance of the carcass," and referring to Dr. Sidney Martin, who gave much attention to the question of "smearing" meat, they add that he "sees no objection to the sale of meat substance from carcases which have shown only localised tuberculosis and from which every particle of tubercle has been skilfully removed."

It is quite unnecessary to discuss with you the question of the urgent need for preventing, by administrative control, the sale of many tuberculous carcases that are now used for the purpose of meat supply, and especially of portions of carcases exhibiting general tuberculosis

or tuberculosis of the internal organs.

I only know of one means, namely, by the abolition, as far as this is practicable, of private slaughter-houses; by the provision in all large centres of population, whether technically styled urban or rural, of public slaughter-houses under the direct control of the sanitary authorities and their officers; and by the adoption of measures which will as soon as practicable, provide a class of skilled meat inspectors.

Another point that has been strongly pressed in recent years, as an administrative measure that is called for in the interests both of justice and of public health, is that of compensation out of public funds to the butcher wherever a carcass is seized on account of tuberculosis, such compensation only to be given in the case of cattle which have cost a certain minimum sum—say £8—and in no case to go beyond a maximum sum of £30.

My main objections to compensation for carcases or portions of carcases seized on account of tuberculosis may be summarised as follows:—

(1) That it is wrong in principle to call upon the public to give compensation to a man who, having made a purchase involving some risk, and having placed the purchased article on sale for his sole profit, subsequently finds that the article in question is not one that, in the interests of the public, he can be allowed to dispose of.

(2) That the risk involved in the purchase of animals of the bovine race, by reason of tuberculosis, is one that

is well known and perfectly recognised.

(3) That, notwithstanding repeated applications on behalf of the Commission to be supplied with evidence showing that real hardship and substantial loss are incurred by butchers by reason of the seizure of tuberculous carcases, the general tenour of nearly all the evidence submitted was in precisely the opposite direction.

(4) That the representatives of the various societies and bodies who urged that compensation from public funds should be accorded to the butchers were almost unanimous in admitting that in businesses extending over a long series of years and often involving tens of thousands of carcases, they had either incurred no less at all owing to seizures for tuberculosis, or any such loss had been altogether trivial.

(5) That such freedom from risk of financial loss in a commercial transaction is hardly to be met with in any

other trade.

(6) That the few exceptions which came before the Commission were almost exclusively limited to a few towns where a standard of excessive stringency had been maintained as to the amount and extent of tuberculosis which called for seizure of a carcass.

(7) That in all these exceptional instances those responsible for this stringency expressed their willingness to abide by any standard which might be authoritatively laid down by a Government department or other authoritative body concerned with the matter of food supplies. Such a standard code of rules has now been laid down by the Royal Commission of 1896.

(8) That even in these exceptional cases by far the majority of seizures had to do with the carcases of cows that had served as milch cows involving special risk.

- (9) That in view of the fact that milch cows have already been a source of profit as milk suppliers, and in order to ensure that profit they have generally been kept under sanitary conditions calculated to lead to tuberculosis, the grant of compensation would tend to encourage the very disease which should, as far as practicable, be prevented.
- (10) That the danger to man of contracting tuberculosis as the result of eating meat from a carcass which, though tuberculous, is otherwise of such wholesome appearance as to justify its being used for a meat supply, is both rare and trivial.
- (11) That the amount of risk really incurred in the slaughter of apparently healthy animals may best be estimated by the fact that some butchers do not think it worth while to pay an insurance fee in order to cover it, which fee would, at the end of the year's transactions, cost them no more than 3d. or 4d per beast slaughtered.

 (12) That, in so far as vital statistics can be relied on
- (12) That, in so far as vital statistics can be relied on to afford any indication of this risk, they go to show that at the ages when meat is most used as a diet, there has not only been no increase of death from tuberculous disease, but that persons living at these ages have been those which have signally profited by the general diminution in death from tuberculous disease which has taken place in this country.

(13) That the large saving of life from tuberculosis at the ages in question has corresponded with a period during which there has been a large increase in the amount of meat consumed.

(14) That any use of Imperial funds for compensation in this matter, on the ground that the protection of the public health is involved, would be contrary to the action hitherto adopted in this country, and under which

measures of public health carried out locally are paid for by the community carrying them out.

(15) That the use of Imperial funds for such a purpose would be liable to open the door to grave abuse.

Public slaughter-houses, officered by skilled inspectors and supervised by medical officers of health, are urgently required, among other reasons, for the prevention of tuberculosis in man. When these have been provided, and rules such as those laid down by the Royal Commission of 1896 as to action with regard to tuberculous cases are uniformly acted on, then this question of the seizure, on account of tuberculosis, of carcases which, apart from that disease, are deemed fit for human food, should, and I believe will, practically cease to exist. The remedy lies, not in resort to public funds for the purposes of compensating a particular trade, but in the adoption of administrative measures of control such as I have indicated.

But if efficient control is to be exercised over the carcases of beasts slaughtered in this country, a control corresponding as nearly as is practicable to that applied at home should be exercised over imported carcasses; otherwise the contrast between laxity in the case of home carcases would be not only unfair, but it might act as an incentive to the transmission to this country of meat which would be condemned abroad.

I would therefore submit for consideration, whether it is not equitable as well as in the interests of public health that skilled inspectors should be appointed at all ports where foreign carcases arrive, and that these officers should be required to select from each ship's cargo a number of carcases for such examination as may be necessary to the protection of the interests of the public. The cost of the necessary staff and accomo dation should in my opinion be paid by means of some trival tax per carcass to be levied on the importers.

Original Communications.

SYPHILIS IN THE ARMY, 1812-1896.

BEING A REPLY TO

MITIGATION AND AGGRAVATION OF SYPHILIS.

By JOHN A. SHAW-MACKENZIE, M.D.LOND.

THE variable intensity of syphilis and its explanation has been the subject of controversy ever since the reputed introduction of syphilis into Europe or its de novo origin at the end of the fifteenth century. Without attempting to go into the disputed origin of syphilis at the present time, it is right to mention that syphilis is said to have existed from the first, and the intensity of disease at the end of the

fifteenth century regarded as an aggravated form.

Not only has the pathology and treatment of syphilis commanded at all times universal attention, but its prevalence and intensity in the Services has been the subject of many reports and especial inquiry. The Report of the Select Committee, appointed in 1879 for the purpose of inquiring into the administration, operation, and effect of the Contagious Diseases Acts, 1866-1869, is well known. One effect of the repeal of those Acts has been

undoubtedly, the discouragement of the teaching and study of the pathology and treatment of syphilis, even sometimes to the mention of or diagnosis of the disease. The whole subject, however, has again assumed, or is assuming, importance in view of the aggravated form of disease in British troops invalided home from India, which formed the subject of a report by a Committee of the Royal College of Physicians in 1897.

The etiology of "Malignant Syphilis" had already formed one of the subjects of debate at the Third

Prof. Neisser, admitting the great diminution of malignancy during the last four centuries, withdraws his previous vigorous adhesion to "congenital immunity conferred by hereditary transmission." He considered there was no substantial proof of this, and attributes the diminution to "increased resistance inseparably associated with decreasing virus activity accruing from adoption of improved methods of treatment the use of antiseptics, greater care in the treatment of local and general manifestations, and improved general sanitary measures. Nevertheless he is willing to admit some degree of inherited immunity, notes the attenuation of measles in communities and countries, and states the following: - "Nor have I noted during the recent extension of syphilis in Russia that an unusual proportion of cases of malignant syphilis has been noted. . . It is interesting in this reference to draw attention to the fact that Epstein has recently recorded a remarkable number of cases of malignant syphilis among the Jews. He is inclined to account for his observations on the hypothesis that the individuals of a community which has been free from syphilis tend to show the malignant type more frequently when at length attacked than the members of a population which has experienced the disease for generations.

In the same year Dr. G. Ogilvie (2), founding his opinion to some extent on the testimony of Professor opinion to some extent on the testim ny of Professor Neumann, considered that "attractive as this theory is by its simplicity and plausibility." both it and the late Mr. Henry Lee's theory of individual hereditary immunity seem "to stand upon a weak foundation." "Ferguson's (sic) statement." says he, that "syphilis has become so much mitigated in Portugal by reason of general diffusion or other causes that after running a mild sion or other causes, that after running a mild course it exhausted itself and ceased spontaneously, has been generally accepted as trustworthy, and been taken over from one text-book to another without further confirmation. It is, therefore, interesting to compare it with the results recently come to by Pro-fessor Neumann, of Vienna. He says. . . . I am by no means in a position to corroborate Ferguson's statements about the particularly benin cases of syphilis in Por ugal, still less that the cases there take a milder course without the use of mercury. On the contrary, in the hospitals of Lisbon I have fully convinced myself that the symptoms are practically identical there as elsewhere. Tertiary practically identical there as elsewhere. Tertiary affections are not rare either. . . . "Unless one resorts," says Dr. Ogilvie, "to the improbable supposition that the relative immunity which Portugal once enjoyed has become extausted, and that thereby a revival of syphilis has taken place, such an experience made by so competent an observer gues far to discr. dit Ferguson's earlier statements. reports from different Russian, German, and English regiments adduced by Ferguson and Lee have, if possible, still less claim to trustworthiness These o' servations, as well as the German and English ones, were made at a time when no distir ction was drawn between syphilitic and other sores. This circumstance slone deprives them of all scientific, demonstrative value. The sad state of the British Army in India is sufficient to shake any theory of general immunity," and, acknowledging the views of

preventive, and therapeutic measures. This paper, containing conclusions obviously founded upon imperfect knowledge of Fergusson's original paper (3) and being prominently noticed (4), led me to draw attention to the original work of Fergusson and work of Rose (5), in support of the former's views respecting mitigation and aggravation of syphilis.

Neisser, "it seems explainable by lack of hygiene,

International Congress of Dermatology (London) in The subsequent discovery by Dr. Ogilvie (6) of a 1896. Both here and in a subsequent publication (1) later paper (7) by Fergusson, in which the latter

Digitized by Google

admitted aggravation of syphilis by the abuse of mercury among the British troops in Portugal, and does not refer to attenuation, seemed to Dr. Ogilvie to prove beyond doubt the correctness of his interretation. Shortly afterwards Dr. Ogilvie's paper upon "Syphilis among British Troops in Portugal, 1812, and in India, 1896," appeared (8), in which his original views are for the most part maintained.

Considerable support was subsequently given to these views in the editorial columns of the British Medical Journal, November 5th, and, notwithstanding the subsequent and for the most part adverse correspondence which followed, the same paper prominently noticed in the editorial columns of the MEDICAL PRESS AND CIRCULAR of January 25th, 1899. In this a direct appeal is made for recognition of this paper, it is further stated that "it has evidently already borne fruit, judging from the fact that the subject for the next Parkes' Memorial Prize will be the "Prevalence of Venereal Diseases in the British and Indian armies"; an unqualified verdict is delivered against Fergusson's statement of the "gradual self-extinction of syphilis in the Peninsula," and support is given mainly to the mercurial abuse theory in explanation of the present aggravated form of syphilis, qualified by the broad theory of improved hygienic conditions and treatment in explanation of

It seems necessary, therefore, that I should again endeavour to represent the work of Fergusson in its proper light, review the grounds upon which Dr. Ogilvie arrives at his conclusions, and submit afresh the factors or combination of factors which have been adduced in explanation of mitigation and aggrava-

tion of syphilis.

Dr. Ogilvie's contentions in this paper are, that the form of disease among the Portuguese manifesting itself as primary ulceration, either local or followed by insignificant throat ulceration, and by affection of the bones often so slight that, but for the previous history, it might be mistaken for simple rheumatism, each and all being curable by antisyphilitic woods and sudorifics, the quantity of mercury being always insignificant and often altogether omitted is (1) not a mitigated form of syphilis due to self-exhaustion, but the natural type of disease; relying largely upon Fergusson's later paper, that (2) the aggravated form of disease seen among the British troops in Portugal was mainly due to the abuse of mercury; and that (3) the present aggravated form seen among British troops invalided home from India may be mainly due to the abuse as opposed to the use of

mercury.
(1a) The difficulty of establishing a standard of syphilis is great. It admittedly varies under different conditions of time, place, and other circumstances, irrespective of treatment. Starting from the admitted intensity of syphilis at the end of the fifteenth century or perhaps before this, under the covering term "lepra," its su sequent lesser intensity has been regarded as modification, and the disease in Portugal among the bulk of the inhabitants depicted by Fergusson must be regarded as a modified form. As, for instance, Wallace, of Dublin, in 1836-8, regarded primary and secondary pustular as the normal type and the exanthematous as the modified. On the other hand, at the present day, the exanthematous eruptions are approximately regarded as the normal, and the pustular as the "malignant." If, however, any importance is to be attached to the descriptions of antiquity, constitutional symptoms are, according to referees, conspicuous by their absence, or nearly so. The local venereal ulcerations alone may thus be regarded as the typical, and anything over these, in the way of consecutive symptoms, as aggravation. The Portuguese local ulcerations, therefore, on such speculative grounds might be regarded as typical

and the disease among the bulk of the inhabitants as depicted by Fergusson, in respect of secondary and tertiary symptoms, as aggravation, and not normal.

Dr. Ogilvie contends that Fergusson made no differ-

entiation between "hard and soft, between infecting and non-infecting sores, between syphilitic and non-syphilitic cases." Dr. Ogilvie omits to say that this kind of argument was dealt with by Rose as well as

by the late Mr. Henry Lee.

'It is reasonable," says Rose (9), "to think that a considerable part of the cases of which Mr. Fergusson speaks could not be regarded by cautious practitioners as venereal, 'but while admitting some of the cases he himself brought forward were not venereal in the Guards he concludes that "among a number of cases of such a description taken indiscriminately the probability of some being venereal is materially increased and must at last approach nearly to a certainty"; while "It is true," says Mr. Lee, "that at the time Mr. Rose conducted his experiments no clear distinction was drawn between those syphilitic affections which if left to themselves would infect the constitutions of the patients and those which would not, and therefore a great many sores were no doubt said to be cured without mercury which under no circumstances would have been followed by secondary symptoms. It is exceedingly probable, however, that a certain proportion of the cases treated by Mr. Rose really depended upon the infecting variety of the disease, and as Mr. Rose found that he could deal with these cases without administering mercury we can only conclude that the disease he was treating had appeared in some modified form such as Dr. Ferguson had noticed in Portugal and such as he states to have existed also in Germany and in Russia.

The syphilitic nature of phagedena and the chancroid are admittedly controversial points. Fergusson, however, distinctly noted a difference between the Portuguese ulcerations and the "trifling cases of chancre as we have seen at home which can often be dried up with a piece of lint, and the venereal ulcerations in the British which were "more intractable to the operation of mercury than under similar circumstances at home." He, moreover, noted a difference between the non-infecting character of phagedæna in certain cases, under certain circumstances, as opposed to those cases "in which the constitution has become affected with the secondary symptoms in a proportion that could not have been expected." The Portuguese, according to Fergusson's later paper, had no phagedæna, at least, he could only recall one case. They were "syphilitic ulcerations." That the British phagedæna was syphilitic is supported by Mr. Hutchinson s statement that ' phagedæna is very much more common in the hard than in the soft sores," as well as by the late Mr. Henry Lee's statement that in acute forms of destructive and phagedænic inflammation " the action which is taking place may save the patient's system from syphilitic infection." As to the non-differentiation between "hard and soft" sores, it is difficult to follow Dr. Ogilvie. "The question still remains," says he, "whether syphilis at the beginning of this century existed in Portugal in a milder form than in other countries. There is nothing in Fergusson s somewhat fragmentary description to foster such a belief. With regard to the primary lesion (including the nonsyphilitic sores), it appears that it was by no means uncommonly mild. Among the forty cases which were at the hospital NONE of the ulcers were such trifling cases of chancre as we have seen at home. . but they were large extensive ulcerations . . . which may prove their apathy, but it does not prove the disease to be a particularly mild one."

Such an admission appears to establish the suppu rative character of these syphilitic sores in contra-

diction to this dualistic argument of Dr Ogilvie and the views of many. Moreover, the diagnosis between "syphilitic and non-syphilitic" cases in these days

is no more certain than in Fergusson's.

(b) "Fergusson, however, inferred as much from its easy cure as from its analogy of the natural small-pox. . . . To prove mitigation or attenuation of a disease in one population as compared to another it is not sufficient to prove that the disease runs a milder course, but it has to be shown that it does so under identical conditions. In this particular case the circumstances under which the respective observations were made were so widely different as to make the observations incomparable." He refers, to make the observations incomparable. of course, to the abuse of mercury under which the British partly laboured, as compared with the treat ment of the Portuguese by their faculty. This argument is of little importance. Leaving the British out of the question, Fergusson, corroborated by Guthrie, notes that "dreadful exfoliations and loss of parts (nose bones) no doubt sometimes occur, but these by no means constitute a large proportion of the affected," and were for the most part noticed in Lisbon. Dr. Ogilvie, it seems to me, would have us be leve that these also were due to mercury, especially drawing attention to Fergusson's first estima-tion of an "adequate' dose of mercury compared with his later view of "a tithe of a tithe, or a centime. There is nothing to justify such an inference. Dr. Ogilvie admits that "its (mercry) internal use was reserved till the disease shows itself in the last order of parts, its last citadel, the bones." And, notwithstanding the fact, which has been authoritatively testified to. that the most serious destruction of parts has followed the non-mercurial treatment Fergusson himself qualifies the term "adequate," as it referred to dosage by the Portuguese faculty, by the statement that such administration was "in an alterative form" and a "ridiculously insignificant quantity of nercury generally of calomel along with Dover's powder, guaiacum, &c.," was given, as opposed to inunction, which Fergusson leads us to suppose in his later paper was practised and abused by himself. The comparison also of the Portuguese disease and treatment with the same type under similar treatment at home, so far from proving the fallacy of attenuation there, begs the whole question as to under what conditions the simple treatment proved efficacious in certain cases.

Far also from the non-differentiation of sores rendering all comparison "vague and worthless," fact remains that there was a difference in the intensity of syphilis among the Portuguese; a comparison sufficiently obvious to Guthrie (10), and which led him, notwithstanding his admitted previous and subsequent practice of, and belief in, the non, or modified mercurial treatment, to state "the secondary symptoms of the most serious nature will occasionally follow in particular constitutions." Dr. Ogilvie does not state that.

With regard to the analogy of the small-pox, Dr. Ogilvie considers such very remote or artificial, and while admitting that little is known of its "selfexhaustion by acquired immunity hereditarily transmit ed," is inclined to think that facts and theory are against such transmission, and that vaccination, inoculation, and isolation are the true explanation. He omits to give us Fergusson's facts in refutation of the same, and which showed that though inoculation and vaccination were well known in Portugal, they were never practised as far as he could ascertain. Nor were there any isolation means adopted, the affected lying apparently unconcerned in the hospitals among the unaffected, &c., nevertheless small-pox was prevalent and a mild disease, and he could not recollect it even terminating fa ally. I believe the same obtains now to a great extent, and that the

popular idea is that the mitigation is due to the "Yet he (Fergusson) had no doubt if this mild disease was transp anted into a prople who had never known it," and I might add into the unprotected among us at the present time in consequence of the abolition of compulsory vaccination, "it would (and will) desolate with all the fury of pestilence.

Nor do s Dr. Ogilvie mention Fergusson's analogy to "all adventitious diseases. . . . that are not connate, endemic. and sporadic, which appear more or less to run this course of exhausting themselves

while retained upon the same ground."

(c) Rose, it is true, regarded attenuation as "as yet me ely hypothesis," and Guthrie, not withstanding his opinion already stated in respect of constitution, is opposed to it. After quoting va ious testimonies, "of course n t all of the same value," including the impression among Portuguese medical men that syphilis has becom- milder during the last thirty years, thanks to hygiene and improved treatment, such information being vouchsafed by a "highly intelligent patient" who writes from Lisbon, Dr. Ogilvie attaches "the greatest importance to that of Guthrie. "We cannot shut our eyes to the fact that not one of these witnesses reports attenuation. This, taken together with Fergusson's later views. will, I think, be ample justification to relegate the allegations with regard to self-extinction of syphilis in

Portugal to the phere of lege dary histories.

Ouviously, none of these report attenuation in favour of the "special pleading" of Dr. Ogilvie, but he does not mention Hennen (11), an equally prominent Peninsular surgeon, who, while subscribing to the non-mercurial treatment, thinks it "proper to direct att ntion to the opinion of those who held," like Fergusson and others previously, that syphilis has "undergone great changes in its nature since the end of the fifteenth century." Moreover, he considered the analogy of leprosy and scurvy was "strongly in favour of such a supposition."

"We have," says he, "also direct testimony which shows that its symptoms have become milder and more tractable. No author is better entitled to speak on the disease than the well-known German, Ulrich de Hutten, if personal suffering can confer such a melancholy distinction. After having suffered for nine years under it (many times salivated and afterwards cured by guaiacum), and we may naturally suppose studied its history minutely, he tells us, in his work published in 1519, that for the first seven years af er its appearance in Germany, it raged with the utmost violence, but that when he wrote its virulence had considerably abated. In 1563, upwards of forty years afterwards, Bernardinus Tomitanus, of Padua, after noting some changes of symptoms which had taken place in the disease since its first appearance in Europe, bears strong testimony to its increasing mildness at the time he wrote. . . . The learned and indefatigable Astruc has collected the authorities of various physicians and historians to the same effect, including a period from 1546 to 1711, to which he adds his own testimony, dated 1735. In it he says, 'I have, by careful and repeated observation, found the venereal disease daily to grow milder; it may, perhaps, be more frequently contracted than formerly, yet its rage is less violent, its symptoms are not so many, so painful, nor so difficult to be cured, it yields more readily to remedies properly applied, and in a word seems little and little to approach towards its close."

A FURTHER CONTRIBUTION TO THE PRACTICAL ASPECT OF INFLUENZA.

By Sur.-Gen. CHAS. R. FRANCIS, M B., M.R.C.P., H.M. Indian Army (retired).

THE retired Indian officer, whose repeated attacks of influenza during the past few years I reported in your journal in 1895, and of whom I predicted that, if he remained where he was-in a house with damp surroundings - other attacks would probably follow, has been twice attacked since I wrote. About the middle of October, 1896, he was taken ill, for the fifth time, with a very severe form of the disorder, confining him to his room for five months. The heart and stomach were involved—the former especially; but the effect upon the nervous system with the weakening, even almost crippling, of some of the limbs, was exceptionally striking. The most of the limbs, was exceptionally striking. remarkable feature in this attack-followed by remarkable feature in this attack—followed by one very similar the next year—has been the gradual though steady deterioration of the nerves shown by slowness both in walking, and writing, accompanied, when so occupied, by an occasional spasm of the hand. He still works at literary pursuits, which give a certain amount of pleasure, but there is now no enjoyment in them. Until quite lately he has remained comparatively Until quite lately, he has remained comparatively well, the several functions being correctly performed; and he has been free from pain. But on the 9th of last month he was attacked with what was, apparently, rheumatism, the limbs being affected alternately with but little power to move them, but with pain when doing so. There was no fever, the urine only being somewhat high-coloured; and the tongue was clean. Influenza was prevalent in the station, assuming, generally, a rheumatic form; so that I am inclined to look upon this attack as a form of this disorder. Althaus, probably our best English authority on the subject, does not indeed give rheumatism as a phase of the disorder, but he describes cases of rachialgia and neuritis as complications or as post grippal; but a case of rheumatism, pure and simple, turning out to be influenza is probably without the pale of medical experience. What favours the theory is the extreme characteristic nerve debility which has accompanied and followed the attack. The patient was well in a fortnight, but the weakness and crippling remain in an increased degree.

The case of this officer seems to afford a good object lesson in teaching, as before observed, that change of air is the best remedy; which is the more especially called for where the original locality is damp. Cases will, of course, occur where this is impracticable; though, whenever possible, it should be adopted. Influenza is usually connected in the public mind with some affection of the respiratory organs. Indeed, till very lately, this was the professional view. The idea of its being essentially a nervous affection is gradually gaining ground with the public, though it is very difficult to convince people of its truth. It was discredited in this case by members of the patient's family, who held to the belief that, being old, he was bound to have something the matter! They told him that, at any rate, he had influenza on the brain! I firmly believe that had the change to a more suitable climate been resorted to when I last wrote four years ago, there would have been no more attacks to chronicle, neither of influenza nor of so-called rheumatism. Granted that it was a genuine attack of rheumatism, previous visitations of influenza doubtless increased the susceptibility of the patient. It may be mentioned that never before, in a long life of seventy-eight years, had there been a suspicion of a rheumatic tendency.

VAGINAL CÆSAREAN SECTION. (a)

By A. DUHRSSEN,

Professor of Gynecology, Univ. raity of Berlin.

FROM OUR OWN CORRESPONDENT.

THANKS to asepsis and Sänger's method of vaginal suture, the old Cæsarean section has lost much of its terrors, so that the indications for it are not confined to absolute obstacles to delivery, but are extended to cases of moderate obstruction. A substitute has cases of moderate obstruction. A substitute has been proposed for the operation in perforation and symphyseotomy. I have substituted vaginal Cæsarean section in one case, and I repeated the operation last year. The description and the results of the operation have already been published in a monograph. It consists essentially in a sagittal published the protein and the results of the operation splitting of the anterior and posterior vaginal culs-de-sac and separation of the bladder from the uterus and splitting of the uterine wall as far as the lower uterine segment, is required. In this way in the first case I was able to extract at term a child weighing 4,700 grm. Puerperium normal. I the monograph I have formulated the three following indications for the operation (1) Abnormalities of the cervix and lower uteri e segment, which render dilatation impossible or difficult. (Carcinoma, rigidity, stenosis, sacculation.) (2) A dangerous condition of the mother, that rendering speedy delivery necessary. (3) Dangerous conditions that will lead to speedy death. It was on this account that I operated last year in a case of mitral insufficiency and dilatation of the right ventricle; in which the nation that preced account that I operated last year in a case of mitral insufficiency and dilatation of the right ventricle; in which the patient had passed several days and nights sitting upright in a chair. There was still some hope if the uterus could be promptly emptied, otherwise it was evident she would die during the course of the labour. when the would die during the course of the labour. The operation was performed as described. The blood was almost black. Easy turning and extraction of an asphyxiated female child; but immediately afterwards the pulse stopped, and finally, whilst attempts at resuscitation were being performed, sutures were inserted, the placenta was removed and the uterus plugged. The operation lasted at most five minutes before the child was visible. The autopsy showed that the operation had been entirely extraperitoneal. In cast of carcinoma, extirpation of the uterus should follow extraction of the child. That this would be successful was shown by a case of rupture of the uterus, which was followed by successful extirpation. The results of other operators who have adopted this method have been even more favourable than my own, when, as I recommended, the posterior vaginal wall was split up. The mortality was 27 per cent., a favourable result when one remembered that in eight out the eleven cases carcinoma was the complication that called for the opera-tion. Some, such as Olshausen, have a horror of the operation because they believe that speedy delivery at term is incompatible with gentle handling, and that gentleman recommended the classical Cesarean section with subsequent removal of the organ. But Olshausen's operation is a much longer one, there is more danger of shock and infection, and more manipulation of intestines. As regards hemorrhage it is free in both forms of operation, but in the vaginal it ceases as soon as the hand is introduced. Drawing down of the uterus and plugging are effective means of arresting hemorrhage. The operation is also indicated when there is premature separation of the placenta with absence of pains, and when the cervix is not dilatable.

⁽a) Abstract of an address delivered before the Berlin Medical Society, January 4th, 1899.

Clinical Records.

CASE OF ECTOPIC GESTATION. (a)

By Dr. Macpherson Laurie, Vice-President of the British Gynæcological Society.

Mrs. W., et. 35, consulted me on September 16th, 1898, on account of pain in the right ovarian region associated with a swelling which she had recognised herself

She had been married for nine years and had three

children, the youngest 41 years old.

The periods had been regular since the birth of the last child until six weeks before she came to see me; since then she had suffered from a constant hæmorrhagic discharge. This was moderate in amount, and latterly partly purulent.

On one occasion something came away having the appearance of a large clot of blood, rather dark in colour, and presumably composed of decidual membrane.

On examination the uterus was found somewhat enlarged and pushed over to the left by an irregular swelling of firm consistency, and rather bigger than an

On September 25th, the abdomen was opened. The right side of the pelvis was occupied by a swelling which was intimately adherent to the intestines. In the process of separation the mass ruptured, discharging a great deal of black clot into the peritoneal cavity.

The abdominal viscers were protected with sponges, the patient raised into the Trendelenburg position, and the clot removed. Separation was cautiously and the clot removed. Separation was cautiously carried out, and completed by passing chain sutures through the broad ligament and cutting through the tissues on the distal side. On further examination, a cavity as large as a hen's egg, and containing blood clot was demonstrated in the ovarian portion of the swelling, and the walls of this space were completed by the expanded end of the Fallopian tube and some portions of adjacent bowel.

Patient made a good recovery.

A report from the Clinical Research Association con-

firmed the diagnosis.

The case seems worthy of record as a possible example of ovarian pregnancy, and I thought it sufficiently interesting to bring before the Society.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, JANUARY 13TH, 1899.

The President, Dr. J. M. PURSER, in the Chair.

PATHOLOGICAL FEMORA AND TIBLE.

DR. KNOTT exhibited a series of nineteen femora pre senting various anatomical, anthropological, and pathological peculiarities of interest, and Dr. Knorr then exhibited a series of nineteen tibiæ, also presenting points of interest.

SPECIMENS EXHIBITED.

Mr. H. Croly: (a) Tumour of the Left Ovary; (b) Specific Fungus of the Testis; (c) Carious Os Calcis; (d) Scirrhus of Breast of eighteen years' standing.

NOTE ON THE AGGLUTINABILITY OF DIFFERENT RACES OF THE TYPHOID BACILLUS.

The SECRETARY (Dr. McWeeney) read a note on this subject. He described how he had been obliged to suspend temporarily the sero-diagnostic work at the Mater Misericordiaæ Hospital, owing to the peculiar behaviour of a strain of typhoid bacilli, called, for brevity's sake, T. A, which he had isolated by the usual methods from the bile of a fatal case of typhoid. Death had cocurred in this case fatal case of typhoid. Death had occurred in this case

(a) Read before the British Gynsecological Society at meeting held February 9th, 1899.

from cardiac failure nine days after defervescence, and at the autopsy the ulcers in the small intestine were healed, but there were many open follicular ulcers in the colon. The bacillus T. A. was present in the bile in great numbers and pure culture. It presented the cultural characters of genuine Eberth's bacillus. Distinctive peculiarities were the extreme slowness of its growth on gelatine plates, the fewness, delicacy, and shortness of the flagella, and the fact that although the mobility was extremely active during the first twelve hours of culture, it had died down by the end of twenty-four hours to a waggling movement hardly distinguishable from that of B. coli. Tested against the serum of several typical cases of typhoid side by side with a typical race obtained from Professor Lorrain Smith, of Belfas*, it proved markedly resistant against agglutinating influences. The dilutions generally practised were 10 per cent., 1 per cent., 2 per cent., and 1 per cent. Sera of cases in the third week, which clumped the Belfast bacillus ("L.S.") instantaneously in 10 per cent. dilution, and left the field quite clear of isolated organisms, took an appreciable time to clump T. A., and after the lapse of half an hour the field was not quite free from scattered bacilli. In the 1 in 100 dilution, where L. S. was well clumped at the end of the observation period (two to five hours), T. A. was so imperfectly agglutinated that diagnostic inferences could not be drawn-in fact, with the higher dilutions these two races of undoubted typhoid bacilli gave directly opposite sero-diagnostic results. The speaker referred to the view that the phenomenon was the result of the interaction of two substances, one contained in the serum, the other in (and subsequently outside of) the bacterial bodies, which played a purely passive rôle; that the serum need not necessarily be immune, nor was the phenomenon essentially specific; and finally, the interesting work of Bordet was described as showing how, quite apart from bacterial action, the serum of the rabbit agglutinated guinea pig's serum containing red corpuscles, causing these latter to form "clumps;" and how, if the serum of the guineapig, which exercises but a slight agglutinative action on the corpuscles in rabbit serum, be taken from a guinea pig which has previously had rabbit's blood injected a few times, the agglutinative action of the guinea pig serum is greatly increased. The bearing of these researches on sero-diagnostic work was pointed out. The paper was illustrated with slides showing the relative size, length, and number of the flagella of T. A. and L. S.

Mr. O'Sullivan said that in a case of Dr. Finny's, in Dun's Hospital, of typhoid fever, accompanied by effusion into the knee-joint, he had isolated bacilli from the effusion which gave the culture reactions, as then practised, of typhoid bacilli, and showed stronger agglutination with the serum of typhoid patients than the stock bacilli which he had at the time. He thought then that this might be due to the fact that the bacilli were more virulent, but it appeared that virulence and the faculty of being agglutinated had no relation to one another. He would like to ask Dr. McWeeney whether, in Krau's experiment, the behaviour of the talchad been examined under the microscope and proved to be a true agglutination and what was known as to the nature of the coagulation of which he had spoken?

Dr. E. J. McWeeney, replying, said that the phenomenon which occurred was one of agglutination and not precipitation.

A CASE OF PERITONEAL TUMOUR.

Dr. Conolly Norman described and exhibited a case of peritoneal tumour. The growth occurred about the junction of the jejunum and ileum, and appeared to spring from the peritoneum covering the anterior wall of the intestine; it was of oval shape, about the size of a goose egg, and in colour and consistence, both externally and on section, strongly resembling an uterine fibroid. The growth had penetrated the intestine, an irregular ulcerated surface, not fungating, and about the size of a sixpence, chowing in the gut. The patient died from repeated hæmorrhages from this point. No other new growths were discovered, and the uterus and ovaries appeared perfectly normal. The tumour was described as consisting of an aggregation of ovoid and spindle-

shaped cells, the former having large granular bluntly ovate nuclei, the latter passing into fibrous tissue in parts. The vessels were very numerous, so that here and there the structure resembled that of an angioma. The tumour could not be made out to be continuous with the muscular wall of the intestine, which it seemed to have destroyed by mere pressure, and, in the opinion of the exhibitor, was to be regarded as a sarcoma, arising probably from the peritoneal blood-vessels.

Dr. McWeener suggested the possibility of the tumour

being myomatous.

R. TRAVERS SMITH thought the specimen was a spindle celled sarcoma, though possibly it might be a myoma, and have originally grown in the uterus, and become separated, and become secondarily adherent to the intestine.

Dr. E. J. McWeeney pointed to certain appearances suggesting that the growth was a fibro-myoma

Dr. A. R Parsons agreed that the tumour might be a

Dr. CONOLLY NORMAN, in reply to the President, said that the tumour was not adherent to the mu cular cost of the intestine. In the central portion of the tumour there was a large number of bluntly-pointed ovoid cells such as one sees in an ordinary quick growing sarcoma.

Dr. Coleman showed a specimen of (a) Glioma of Cerebral Hemisphere; (b) Tuberculous Tumour of Cerebellum; (c) Abscess of Cerebellum.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, February 19th, 1899. THE TREATMENT OF UREMIA BY INJECTIONS OF SERUM IN THE RENAL VEIN.

AT the last meeting of the Lyons Medical Society M. de Lignerolles gave an interesting account of his treatment of uramia by injections of serum into the renal veins. The kidney, he said, possesses an internal secretion which it pours into the organism by means of its efferent vessel. The importance of the antitoxic role of that secretion against hurtful substances that the kidney could not eliminate had been demonstrated by numerous experiments and by clinical facts. To remedy that renal insufficiency Brown-Séquard, Meyer, Ajello, and Parascandalo injected in animals deprived of their renal organs the diluted juice of kidney extract; they obtained in uræmic troubles very favourable results, which confirmed the clinical observations of Dieulafoy, Teissier, Donovan, and others. But "would it not be better," asked Brown-Sequard, "to employ the venous blood of different parts of the organism than the extracted juice of these parts. The venous blood coming from an organ contains, in fact, the principles of the internal secretion special to that organ."

This conception, which had already guided Meyer in his experiments on the periodic respiration of Cheyne-Stokes, had been realised by Prof. Vitzou, of Bucharest. The remarkable cases of prolonging life which he obtained in animals, from which the kidneys had been removed by injections of defibrinated renal venous blood, encouraged Dr. Turbure to treat in the same way patients suffering from uramia. Under the inspiration of Prof. Teissier, the speaker made a special experimental study of the treatment at the hospital.

The blood of the renal vein of a young and healthy goat was drawn under perfectly aseptic conditions, and its serum decanted into small six drachms bottles. The toxic properties of the serum were insignificant, especially when the liquid was injected into the subcutaneous cellular tissue.

The cases he presented to the Society were not numerous on account of want of time, but such as they were they merited attention, not only on account of the nove'ty of the method but also, and what was more important, by the constancy of the results obtained The first case was that of acute nephritis complicated with uramia. The patient, a boy of 15, entered the hospital suffering from anasarca, the result of scarlatina-The urine contained a large quantity of albumine, leucocytes, and cylinders. Vomiting was persistent. The symptoms became so grave that an injection of six drachms of the serum was made in the right flank. The following morning the improvement was considerable; the violent headache had subsided as well as the vomiting, and four days afterwards the œdema had disappeared, while the urine, rare before the injection, returned with great abundance. All trace of the albumen had disappeared at the end of a fortnight, and the patient rapidly gained strength. Another case was that of a woman, æt. 60, who entered the hospital with signs of chronic nephritis (bruit de galop (heart), a large quantity of albumen in the urine, diminished renal permeability). An injection of the serum of the renal vein produced a very notable improvement in all the symptoms, and in the general condition of the patient. Here also the albumen disappeared.

The details of the following case were furnished to the speaker by Prof. Turbure, of Bucharest.

Nicholas V., æt. 27, entered the hospital with gene ralised anasarca; the legs were swollen to the abdomer and the patient complained of frequent micturition thirst, headache, pains in the back, and tingling sensation in the fingers. The lungs, heart, and liver appeared sound. The urine contained albumen, and was very abundant (5 litres). In a few days these symptoms grew much worse, the headache became excessively violent, dyspnœa set in, and finally he was s ized with tonic convulsions, in spite of the application of repeated wet cupping. The quantity nor the quality of the urine could not explain these phenomens, what was wanting was the internal secretion of the kidneys, whose office was to neutralise the toxins accumulated in the organism This point was remedied by injecting under the skin of the patient three drathms of defibrinated renal venous blood drawn from a strong and healthy dog. A few hours later the patient became calm, and asserted that he felt much better. Four days afterwards the headache returned, but yielded to another injection, and the urine diminished by a third. A few days afterwards the patient insisted on having another injection, and in all six were given with constantly improving results, so that at the end of six weeks he left the hospital cured.

In summarising the effects of the treatment, M. Lignerolles said that the effects of injections of six drachms showed themselves in general a few hours after the injection. The violent headache was the first to disappear, while the nervous troubles, prostration, weakness, melancholy, delirium, gave place rapidly to gaiety sometimes exuberant the vomiting ceased after one injec. tion, and the oppression or dyspnæa was eased in a very short time while the urine, rare before the injection, became very abundant under its influence, with consequent removal of the cedema.

From all these facts he would conclude that injections of the serum of the renal vein could be employed with

success against the uramic complications of nephritis, and could contribute to the improvement of these maladies, as he had several times observed. They furnished to the organism the internal secretion wanting, and allowedthe kidney to recommence its normal function of excre tion and its anti-toxic role.

Germany.

FROM OUR OWN CORRESPONDENT.]

BERLIN, February 18th, 1899.

AT the Society for Innere Medizin Hr. Bendix showed a case of

RECURRING ERYSIPELAS.

Two months before, the patient had been admitted into v. Levden's klinik for erysipelas of the face, hairy scalp, neck, and upper part of the trunk. This was the tenth attack of erysipelas that the patient had suffered from. After the fifth attack the face, but especially the upper lip and the chin remained swollen. The skin was not affected by inflammatory changes, its colour was normal, was firm to the touch, and left no pitting on pressure. As a result of the erysipelas a pachydermatic process had taken place in the shape of a chronic lymphatic edema that had become organised. Therapeutically, it was probable that systematic massage would be tried.

Hr. Jastrowitz said it was a curious fact that some people had a tendency to erysipelas, as all recurring cases showed. In earlier cases it was believed that there was a connection between the erysipelas and liver affections.

Hr. Ohrtmann some years ago had seen two cases that were treated with Fowler's solution, and after this they had no return of the disease.

Hr. A. Fraenkel believed that individuals specially disposed to erysipelas harboured virulent streptococci in their nasal cavities for a long time, just as individuals with a tendency to pneumonia harboured virulent pneumococci in the cavity of the mouth.

Hr. Bernhardt had some time before published the history of a similar case. With this lady after any great excitement erysipelss of the face came on, although without any new infection. Thus on one occasion when some curtains took fire at home she was frightened, and in an hour the erysipelas was there. Her case was often demonstrated, and every time she became excited and got erysipelas. In such cases there were exaggerated excitability from vasomotor system without infection.

Hr. Ohrtmann had frequently had to treat a wellknown deputy for erysipelas that affected the whole of the head and always lasted some weeks. The attacks always came on when in the course of his public life he underwent any great excitement.

Hr. Gluck believed that in cases of recurring erysipelas depôts of streptococci remained in the lymph track. In cases in which streptococcic collection had been removed after suppuration there had been no recurrence

At the Society for Psychiatry and Nervous Diseases, Hr. Valentin related a case of

PACHYMENINGITIS WITH TABES ON A SYPHILITIC BASE. The patient was a merchant, æt. 46, who in 1870 had a hard chancre, and was only treated locally. In 1889 he had gastric crises and lost flesh. He underwent various courses of treatment without effect. In 1892 Remak

diagnosed incipient tabes; in 1894 the patient got worse. Along with other symptoms there was giddiness and diplopia. In 1897 there was paralysis of all four extremities. There was violent pain in the neck. The patient was admitted into the Nerve Klinik of the Charité. He was a big, strong man. There was pressure pain over the whole length of the spine. The movements in the knees, feet, and toes were only very slight. With the eyes closed there was ataxia. Patellar reflex on one side present, on the other exaggerated. The head only slightly movable. He could swallow, speak, and move the tongue, the sensorium was free. The pupils were unequal, not acting to light; but reacted accommodation. There were disturbance of feeling and sensibility. Strong Faradic currents were not perceived in the arms. With inunction of potassie iodide the movements improved. Later the patellar reflexes disappeared, and the patient died of decubitus, cystitis-&c. On section macroscopic syphilitic changes were found in the liver and heart. In the upper part of the cord the meninges were adherent, and there was sclerosis of the lateral columns. Below this the changes were not so marked. Both grey and white substance was diseased in the dorsal spine. The syphilitic disease was very evident in the arteries.

At the Medical Society Hr. Plonski showed A CASE OF CHANGE IN THE SKIN PRODUCED BY RONTGEN RAYS.

The case differed from those previously shown by him, inasmuch as the time that had elapsed was longer, Two and a half years ago the patient was a stenographer in a large electro-technical institution, and volunteered to submit to experiment with the radiograph. At first no harm was done, but at last inflammation of the skin took place, partly of a malignant character. After the parts had healed further changes took place in the cicatrices. Innumerable new growths of vessels were seen around the white cicatrices, so that the whole back, for a space of two hand-breadths in width looked like a large red patch not unlike teleangiectasis. There was a similar appearance on the hands. Associated with this were subjective disturbances, intense itching from 1896 increased from year to year, on the hands a feeling of coldness, and they became more easily tired than before. Sensibility was slightly diminished. Therapeutically the speaker would probably reduce the vascularity by electrolysis, and recommend massage and hot bathing. To avoid such changes, the tension of the current should not be too high, the time exposure should not be too great, and the parts should not be brought too close to the Crooke's tubes.

At the Dermatological Society Hr. Joseph read a note

CHELOID

Whilst Kaposi made a distinction between true and false cheloid Unna saw in every one a cicatrical cheloid, and in the absence of visible injury, assumed an unimportant one (scratch wound). The speaker extirpated one that had arisen in a cicatrix where union had taken place by first intention. There was no recurrence. section of the tumour in series there were no foreign bodies. It showed peculiar septs. It appeared as if the cells of the tumour lay around lymph vessels, and the sept formation was caused by their crowding around the lymph tracts. The lymph vessels themselves were often destroyed. It was possible that a

portion of the cells had wandered out of the smallest blood-vessels, and by their growth had given origin to the tumours. Plasma cells, and elastic fibres were present in true cheloid, but not in cicatricial cheloid. The elastic fibres of the tissues pressed upon by the cheloid were destroyed, either by pressure or by a chemical process. Elacine was not present; but it appeared as if the collageni basic substance underwent hyaline degeneration. In a case of cicatricial cheloid there were no tumour cells two years after removal. Papillary bodies were absent in all cicatricial cheloids and hyperplastic cicatrices. True cheloid, on the other hand (Joseph's case sprang from the skin over the breastbone), showed a well-developed papillary body. The tumour consisted of spindle-celled fibres. There was no recurrence.

A large number of preparations were shown.

Hr. Lesser had met with a similar condition of things in a case of acne cheloid in a negro. In spite of extirpation through healthy tissues, and covering the defect by a flap, the disease had returned.

Austria.

FROM OUR OWN CORRESPONDENT.

VIENNA, February 18th, 1899.

HYDROCELE AND EVERSION OF THE TUNICA VAGINALIS. In November of 1895 Prof. Doyen published a paper on the Radical Cure of Hydrocele by Everting the Tunica Vaginalis. This operation, he tells us in that paper, had engaged his close attention since 1890, when he first performed it in a case of obstinate, constantly recurring hydrocele, which proved a success, and induced him to practise it in other cases, which he did for five years. The radical principle of the operation is to destroy the cavity of the tunica vaginalis by removing the posterior sheath of the vaginal covering instead of the outer fold. In order to do this the operation is performed by entering the tunica along the seminal ducts posteriorly, as described by Doven, as follows: -

First Stage.— An incision about an inch long (3 cm.) in the upper and anterior half of the scrotum. With a blunt sound the edges of the wound are separated, allowing the tunica vaginalis to protrude in the form of a hernia from the wound.

Second Stage.--Puncture and eversion of the tunica vaginalis: With a bistoury the tunica is punctured and the fluid drained off. The puncture is next enlarged with a pair of scissors towards the duct to the extent of an inch, through which opening the testicle is pressed out and with the point of the finger passed along the seminal duct. He separates the tunica and returns the testicle. In some cases Juvara, who has recently performed many of these operations, tells us that the wound of the tunica vaginalis can be too large to allow of return, in which case he applies a stitch.

Third Stage - The wound is now closed with catgut suture and compression applied, or dressed with iodoform and collodion and enveloped tightly in a cotton wool suspensor. In two or three days the patient may leave bed and in seven or eight the would is quite healed.

Juvara performs the operation sometimes under general anæsthetic and sometimes with only local anæsthesia.

In cases of very large hydroceles simple eversion and twisting is not enough, as the large tunica is cumbrous

and must be resected, leaving the portion around the

This operation has many advantages over the older forms of treatment, and can be easily performed by any surgeon, and may be accomplished in three or five minutes. The simple operation of injecting iodine tincture takes longer time without the security of success.

In the eversion method all those grave complications are avoided which attend the tincture injection, as complications in the former seldom ever arise, even in total resection; in the latter a hæmatoma may take place, but in simple eversion, without resection, no hæmatoma can occur as no vessels are cut.

HYDDROPS GENUS INTERMITTENS.

At the Medical Club, Bum showed a patient, a merchant, æt. 37, who, seven years ago, suffered from neurasthenia, pains in back, &c. A few months ago a cyclical form of dropsy commenced in the right knee. The swelling has no pain; increases for three days, and then gradually declines in the same time. No other morbid condition can be discovered. No medicaments for neurasthenia have any effect in checking or modifying the repetition. He collated similar cases from the literature of Seeligmuller, who is inclined to classify such cases under the head of Vasomotor Neurosis, although the ætiology of the disease must yet be acknowledged as obscure. Heredity, according to some French authors, is not without its influence.

Schliesinger told the meeting that he had another similar case under observation, who for the last six years has had periods of suffering regularly every two years Attacks of three days' duration with remissions of ten days occurred during the months of November and March. At the onset of the disease strangury is persistent, causing the patient to urinate every few minutes. The quantity of urine passed in twenty four hours is great, although very little is passed at a time. During the attacking months, November to March, the upper extremities become astonishingly emaciated, but rapidly recover after the attacks have ceased to recur. This patient is not neurasthenic. He says he has been able to keep the attacks off since he has become a vegetarian!

Continental Bealth Resorts.

[FROM OUR SPECIAL CORRESPONDENT]

MONT-DORE. - (Puy-de-Dome).

THE number of British invalids seeking the health resorts of Central France has for several years been gradually decreasing; but for Mont-Dore at least (judging from the past autumn) the tide is apparently turning, and this station of ancient celebrity promises to be more than ever popular with our countrymen.

It is easy of access from Paris (by either the Paris. Lyon-Mediteranean, or the Orleans railroads) and now the branch railway from Laqueuille to La Bourboule and Mont-Dore dispenses with the one and a half hours' carriage-drive, often objected to as a tedious termination of a long journey from Calais or Boulogne. Some, however, may be old-fashioned enough to regret the "improvement." For that drive was one of beauty; winding up and down along wooded slopes with glimpses of lovely landscapes, and occasionally, bits of grander scenery.

Nowadays we talk much of altitudes when comparing health stations. Mont-Dore is the most elevated thermal resort in central France, being 3,418 feet above sea level, almost approaching the Alpine zones. Around the narrow valley in which the town lies rise the highest summits of Auvergne—the Puys Gros and Angle, and the Pico Sancy, and Capucin. The Sancy peak has an altitude of 6,190 feet.

A multitude of picturesque spots are in the immediate neighbourhood. The readily accessible Capucin heights, the Gorges d'Enfer, Lake Guery, Chambon, and Pavia, the cascades of the Dore, and the Dogne streams at the foot of Mount Sancy, and those of Queureilh, Rossignolet, Saut-du-Loup, Plat-â-Barbe, Vernière, Serpent, &c There need be no idle days at Mont-Dore for visitors who love Nature in any of "her various moods"; for those who like leaf, flower, or insect-gathering, geological jaunts, archeological trips, sketching, or photo graphing. And for the less active and more lazy during the months of the "high season" (July to September), are the Casino, theatres, cafés, ball-rooms, reading-rooms, and other town amusements, with abundance of fashionable attire, promenading, seeing and being seen. Pleasure-taking, hobby-riding, and health-seeking can go all summer and autumn hand-in hand continually in "old Auvergne!

Mont-Dore, said one American physician, ' is popular with priests, clergymen, actors. and artists." To pass part of an August afternoon in the really artistic halls galleries, and salons of its Thermal Establishment is to recognise fully that Mont-Dore is then equally thronged with all other "sorts and conditions of men,' and more than equally thronged with the priestesses and devotees of fashion and elegance "flitting gaily around, dricking gargling, or sipping the waters" in the intervals of healthful strolls and lively gossipings. Those who prefer the greater quietude should come before July 14th, or after August.

The mean average temperature of summer does not exceed 54° Fahr. The average of the barometer (during the Thermal season) is only $26\frac{6}{10}$ ins.; on the coast it is $29\frac{9}{10}$; thus showing considerably less weight of atmosphere at Mont-Dore than at the sea-side.

The average temperature in June, July, and August is 60 Fahr. Evenings and mornings the air is usually fresh; only becoming heated about mid-day, when generally are breezes from the hills and valleys preventing disagreeableness. Occasional storms are of short duration, and cause no inconvenience, simply lowering the temperature for a time. The pointed mountain peaks guard the valley from electrical disturbances.

The winter climate of Mont-Dore is cold; the summer climate temperate and strengthening; the Bath establishment is one of the finest in France; and is completely equipped with all modern appliances for the most efficient uses and applications of the mineral waters. It consists of two separate bui dings, connected by a covered bridge. One building is for vapour treatment, with rooms for inhalations and pulverisation for men. The other building (recently rebuilt at a cost of £120,000) contains the baths. It is erected over the springs, and has many galleries for baths, douches, inhalations, pulverisations, nasal-douches, foot-baths, and two hydropathic apartments. Two staircases, on the right and left, ascend to the first storey, leading into a very large

polished Vosges granite; each column, cut from a single block, being 27 feet in height. A main gallery leads from this grand central hall to the various baths and to the celebrated "Cesar Spring." Built into the walls and foundations of the establishment are numerous remains of ant que baths, temples, mansions, sepulchral-stones, parts of statues cut from porphyritic lava, and other vertiges proving the great use of these springs in Roman and even pre-historic ages. The primitive piscines of the Gauls are yet visible, and side by side with them portions of the extensive Roman Baths. During the Middle Ages the springs were apparently neglected; to be brought again into popular use in 1605. The prosperity of the present station dates from the days of Dr. Michel Bertrand (1810).

The Operating Theatres.

ST. THOMAS'S HOSPITAL

OPERATION FOR ELFPHANTIASIS OF SCROTUM AND PENIS -Mr Battle operated on a man, æt. about 45, a seaman. who had been sent to the hospital from the South Coast suffering from swelling of the penis and scrotum. Although he had b en abroad he had never been in the tropics, his longest voyage having been only to Hamburg. He had noticed gradual swelling of the penis and scrotum, which had been coming on painlessly for a period of some months; it had become so large that it interfered considerably with his getting about, and the scrotum and skin of the penis were much enlarged, the skin of the scrotum being such as described in accounts of elephantiasis met with in foreign parts; it was very heavy, and easily indented with the fingers 'The penis resembled more the condition of the penis as seen in chronic dropsy, the skin being but little affected. There were, however, no signs of dropsy in other parts of the body, nor of any disease to account for it. At the operation a greatly elongated prepuce was slit up along the upper surface and the glans exposed. The skin, which was diseased, and the subcutaneous tissue were then removed. There was not much bleeding An elastic band was then passed round the base of the scrotum. Two flaps were then fashioned, one from each side of the scrotum, from the tissues which had been dragged down by the weight of the part and which as yet presented no change. Numerous vessels required ligature when these incisions were made. The testes were then sought for and isolated from the other tissues after which the remainder of the scrotum was cut off well above the diseased portion. During the operation there was a great escape from the cut tissues of watery fluid, so that the weight of the tumour was much reduced before it was finally removed. The two flaps were then united in the middle line forming abundant covering for the testes; no attempt was made to bring a covering over the denuded penis. The usual dressings were applied. Mr. Battle said that during the patient's stay in the hospital before operation the blood had been frequently examined for the filaria sanguinis, but none were found, and, although the case was evidently one of elephantiasis, there was no excessive enlargement such as might be seen in several recorded cases. The case was interesting hall, with a roof supported by eight great columns of from the absence of anything like a chance of catching

the filaria by visit to the regions where it is known. The hæmorrhage would have been very severe had it not been for the use of the Esmarch's band.

The patient made a satisfactory recovery, the penis granulating over and becoming covered with soft cicatrix.

Vital Statistics.

THE deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 219 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of the year 1899.

Birkenhead 21, Birmingham 22, Blackburn 16, Bolton 24, Bradford 17, Brighton 14, Bristol 21, Burnley 11, Cardiff 16, Croydon 15, Derby 20, Dublin 31, Edinburgh 27, Glasgow 35, Gateshead 18, Halifax 20, Huddersfield 16, Hull 16, Leeds 20, Leicester 16, Liverpool 30, London 22, Manchester 25, Newcastle-on-Tyne 19, Norwich 15, Nottingham 24, Oldham 25, Plymouth 20, Portsmouth 20, Preston 32, Salford 22, Sheffield 19, Sunderland 27, Swansea 22, West Ham 16, Wolverhampton 20. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 1.0 in West Ham, 1.6 in Manchester, and 1.9 in Bolton; from scarlet fever 1.1 in Sunderland; from whooping-cough, 15 in Bristol, 18 in Sundrland, and 25 in Cardiff; and from "fever," 27 in Preston. In none of the large towns did the deathrate from diarrhea reach 10 per 1,000. The 118 deaths from diphtheria included 49 in London, 10 in Leeds, 8 in West Ham, 7 in Sheffield, 6 in Birmingham, 6 in Liverpool, 4 in Edinburgh, 4 in Leicester, and 3 each in Giasgow, Cardiff, Swansea, and Manchester. No death from small-pox was registered in any part of the United Kingdom.

THE HUNTERIAN ORATION.

From the year 1814, almost annually till 1855, and since then biennially, an orator has been appointed by the Council of the Royal College of Surgeons to

extol the virtues and maintain the verdure of the memory of John Hunter. Possibly, therefore, no pioneer of medical science, not excepting the immortal Harvey, has been made the object of so much adoration on the part of a grateful posterity. As a matter of fact, an oration upon John Hunter has been delivered upon fifty-nine occasions, and among the orators are included m st of those whose names are indissolubly associated with the progress of surgery in this country. But no one can dispute the worthiness of the panegyrics which have been bestowed upon Hunter-for anything Hunterian is naturally endowed with an interest which time can never diminish. Reflect, for a moment, upon his remarkable personality. There was nothing commonplace about him; his habits, modes of thought, enterprises, indomitable energy-everything was original. His life was one unresting, ceaseless exercise of mind and body. The few hours which he is said to have allowed himself for sleep at nights seemed to have been begrudged by him, and at the zenith of his work were probably often interrupted by sudden flashes of thought bringing in their train suggestive and attractive problems. In these days it is almost impossible to conceive of a man of Hunter's energy and indomitableness. The conditions, indeed, of present day life are probably entirely unsuited to the existence which he adopted; moreover, Hunter lived at a time when the field of human knowledge was vastly limited in comparison with that which is now the case. He appeared on the scene when, so to speak, an unexplored country of virgin land lay open before him, and, as a pioneer, imbued with confidence in his own capacity, he set himself the task of tilling it, and of proving the value of the crops which it could produce. It is doubtful whether any man, in the world's history, has, in his lifetime, added so much to the sum of human knowledge as did John Hunter. There is, then, nothing surprising in the fact that successive Hunterian orators should find that the record of his wonderful life will bear the retelling without losing in interest or attractiveness. The oration delivered before the Prince of Wales at the College last week by Sir William MacCormac is an instance in point. A tone of sympathetic admiration pervades it throughout, and mingled with the many instances of stupendous investigations which Hunter undertook are subtle reflections upon his many sided character which throw further light upon the genius which Hunter was. In alluding to the portrait of the great surgeon by Sir Joshua Reynolds, which adorns the theatre of the College, the orator said as follows: - "As we look at the picture, painted in 1785, when Hunter was fifty-seven years old, we perceive him in deep reverie in one of those waking dreams to which he refers in his lectures. He has paused from writing in order to think out some problem, and as he often said, it was a delight to him As we dwell upon his features, we cannot doubt that a sudden inspiration has flashed upon and gradually pervaded his mind, some great

scientific truth or generalisation which he has grasped and is pondering with intense satisfaction. Those eyes, full of the keenest intelligence, seem in eager quest of something far beyond the visible tokens of his work. We may imagine Hunter trying, perchance, to solve some hidden mystery of life or seek ing to pierce the veil which hides from us the great unknown beyond." This fine tribute to the great surgeon, as well as to the great painter who reproduced his features, will alone make the Hunterian oration of Sir William MacCormac memorable. Last Tuesday week was by no means the first time that the Prince of Wales listened to an Hunterian oration, but we can conceive that His Royal Highness could not fail to have been interested in the record of Hunter's life which Sir William placed before him.

THE TUBERCULOSIS CRUSADE

THE public interest in the subject of tuberculosis has at last, we are thankful to say, been fully roused, with the gratifying result that endeavours are being made in every quarter to do something to abate this terrible scourge. A few weeks ago the Medical Institution, which fully represents the medical profession in Liverpool, had an interesting discussion on the subject, the result of which was the appointment of a special sub-committee to draw up a report and present it to the Institution. The Committee dealt with the subject in a most exhaustive manner, and the report they have issued is full of useful suggestions for the prevention and treatment of the disease in all its stages. The text of the report consists of four subdivisions, and refers in the first place to the diffusion of information for the general public-There can be little doubt that before much can be expected in a progressive direction the co-operation of the public must be obtained, and as the disease is more prevalent in the poorer quarters of a city, this information must be distributed by handbills or leaflets, in which are set forth the main points regarding the precautions to be taken. The handbill drawn up by this Committee is excellent, containing a lot of useful information in a few well-chosen and easily intelligible sentences, and the Health Committee propose to issue several thousands among the poorer classes of the community. They are printed on stiff cardboard, so that they will not be destroyed readily. The sec ion which deals with the sources of infection lays special stress on the good work which has been done hitherto by the Corporation of Liverpool in destroying and demolishing insanitary property. Perhaps the day may come when it will be found practicable to provide the working classes with houses in the suburbs of large cities, but the problem is a most difficult one, and is not favoured by the industrial classes themselves. The most important part of the r-port, however, deals with the treatment of tuberculosis in its early stages, and recommends the provision of sanatoria in some healthy and suitable localities. There can be no possible doubt that if early cases of phthisis are placed under proper conditions they will recover, if

not, they drift to a certain death, at the same time distributing out the germs of infection to all around who are susceptible to the disease. We are glad to know that the guardians of the poor of Liverpool are to hold a conference with the view to providing such a sanatorium for the tuberculous poor, and this is a decidedly progressive step, and one that can be emulated by every Poor-law authority in the country. The Committee also recommend that wards should be set apart in every hospital for tuberculous cases, thus reducing the risk of infection to other patients With regard to the notification to a minimum. of phthisis, the Committee do not recommend such a step at present, although there are many reasons in favour of such a proceeding. Consumption being an infective disease, clearly ought to be treated as other such diseases, and we have no doubt when the mind of the public is thoroughly educated to the subject notification will follow as a natural sequence. Another important point is the disinfection of houses in which tuberculous patients have lived and died. This is most essential and we are glad to see that the Medical Officer of Health has consented to carry out all such disinfection of clothing and houses free of cost. Altogether the report is carefully drawn and reflects credit on the Medical Institution, who are thoroughly alive to the importance of the subject, and are making an honest endeavour to grapple with a problem which will we have no doubt be satisfactorily solved in due time.

HISTORY BASED UPON DIET.-III.

FURTHER consideration of this subject may be directed towards the apparent relationship between the form of food and the disposition of the eaters, regarded in mass, not in particular. All statements on a subject so wide as this is, cribbed and confined within the space available here, must be understood to be only applied in the most general sense. The various and complex circumstances which influence more or less strongly the applicability of general laws to individual cases, though individual here may represent considerable numbers, assuredly merit much additional argument. The disturbing factors are innumerable, but taken all over, they neutralise the deductions derivable from their action in one instance, by altered effect in another. The spirit of cruelty the love of torture, these are surely not qualities high up among the rungs of the neurotic ladder. The meatloving nations, however, are no more cruel than the vegetarian peoples. The lack of appreciation of cruelty was no more decaly conspicuous in the brains of the Red Indians of North America than in the ascetic, supposedly half-starved cerebral tissues of the Roman Catholic monk or inquisitor; while the American Indian could give the natives modern southern Europe points in affection for and kindness for their domestic animals. The Mahomedan, the Chinese, even the mild Hindu are surely not any less callous of causing suffering than the inhabitants of this country; they are probably more cruel, even though the first-named is supposed to

abhor the juice of the vine and its protean poisons. The tribes in many parts of Africa and the Esqui maux in Greenland live principally upon flesh, but the first may prove truculent and cruel, the second are mild-mannered men. In neither instance have the higher qualities of the brain benefited from the animal food, in both its procural takes up too much time, while, in the one a more vegetable diet would suit the climatic environment better; in the other the difficulty of obtaining the food is of an extraordinary kind. To take a more modern instance. The statement may be hazarded that the nature of the diet has to do with religion. The more absolute the religious power exercised by the clerical officials over a race or nation, who have themselves appointed their clerics, the less is their food adapted for the higher development of their mental centres, dependent, of course, upon their environment. In Europe and America the Roman Catholic nations are chiefly those which eschew or have to be sparing with flesh. In the United Kingdom the same tendency is apparent. The humbler Irish, fed so largely upon vegetable food, con. trast with the Scotch, even if the latter be allowed only porridge. Oatmeal is above potatoes. "Sandy" is no doubt deeply religious, but his religion is personal, independent; "Paddy" trusts and is swayed by one of his fellows initiated into religious mysteries which are withheld from him, and is religious by proxy. "John Bull" follows also an independent line for the greater part. To conclude this series of articles, bearing in mind that every suggestion is only to be regarded as based upon the broadest lines, a study of the history of the nations apparently justifies the dictum that diet rules the world. During mankind's nursery days his greatest advance and power naturally accompanied his opportunities of getting food, of living most easily, and of lack of struggles with the elements. the fact that the food which is most suited to a temperate climate, along, no doubt, with several additional aids, is most fitted to develop the higher cerebral faculties, irresistibly influenced national history, influencing it gradually through many stages, each stage, however, a link in the chain leading to the present balance of racial power. It is never safe to prophesy, but we would venture to doubt the occurrence in the future of any prolonged predominance of a race living in the warmer climates, even after the natural decadence of the present northern Powers, induced by over indulgence or by Malthusianism. Given equal opportunities for the obtaining of food and for the education of her people, a nation living in a temperate climate, and consuming flesh in the proportion permissible while living in it, will infallibly advance beyond nations of warmer countries and sparer flesh-eaters.

WE regret to hear that Professor William Rutherford, of Edinburgh, is seriously ill, but we are pleased to be able to add, that the latest reports are more reassuring.

Aotes on Current Topics.

Death in a Padded Room.

Last week an inquiry was held concerning the death of a patient at the London Hospital under somewhat unusual circumstances. From the evidence of various witnesses it appeared that deceased broke his ankle as the result of an accident, and after admission to the ward he developed delirium tremens. He was then transferred to a padded room, and restrained by means of straps or "shackles," and was kept under those conditions until his death, on the third day after admission. An occurrence of this kind in one of our great hospitals is no more creditable to the management than it is in touch with modern scientific principles of medical treatment. First and foremost, the act of transferring a delirium tremens patient to a padded room will be regarded by many medical men as well night indefensible. Desirable as it undoubtedly is to keep sick wards free of delirious patients, yet it by no means follows that they should be removed to a padded room. The use of such a place for such a patient sounds like an echo of the bad, old hospital days. Surely in a place with the resources of the London Hospital it would be possible to have an isolation ward with an ample staff of nurses for emergencies of the kind, a certain percentage of which must arise from time to time. The house surgeon is reported to have said that he could give the deceased no medical aid in his condition, and that the only thing to do was to keep him quiet. A statement of that sort could hardly come from a medical man about a condition in which active medical treatment is conspicuously successful in saving life.

Foreign Bodies in the Stomach.

THE newspapers report a curious case in the Peter. borough Infirmary. An itinerant juggler is said to have presented himself with the statement that he had swallowed a number of pebbles in the course of his conjuring entertainments. This statement was confirmed by the recovery of some sixty stones, some as large as a pigeon's egg, weighing altogether about a pound and a half. The conjurer is to be congratula ed on his escape, for recovery under such circumstances is often doubtful. Not many months ago a famous American juggler found himself unable to empty his stomach of its wented lead of nails, coins, of chain, and other metallic articles, which he had swallowed by way of public entertainment. An X-ray photograph revealed the foreign bodies as a large diffuse mass in the abdomen. The weight of this indigestible load stretched the stomach and pulled it out of position to such an extent that one day he was unable to expel its contents, as he had previously been in the habit of doing. Gastrostomy was promptly performed, but the patient died shortly afterwards, a monument of human folly. The folk who flock to a repulsive exhibition of this kind are to be condemned more severely than the unfortunate victim who has sacrificed his life in pandering

to the heedless and morbid curiosity of mankind. Why does not the State control public performances in fact as well as in theory?

Tuberculous Infection and Second-Hand Clothing.

THE bye-ways by which tuberculous infection may be conveyed are being investigated with a keenness in the present day which leaves nothing to be desired And, after all, the value of the crusade against tuberculosis will almost entirely depend upon the perfection of the methods of prevention which it may bring into vogue. With a perfected, regular, and universal system of prevention, tuberculosis as an infective disease may, in time, be relegated to an obscure position in the list of ills to which human flesh is heir. As showing, however, the activity now prevailing among bacteriologists and others in investigating all possible channels of tuberculous infection, reference may here be made to some interesting observations upon second-hand clothing recently recorded by Dr. W. G. Bissell, Buffalo (U.S.A.). In the health department of the town with which he is connected he noticed that several of the officials had to cease work in consequence of tuberculosis. At that time the uniforms and overcoats, when discarded by an outgoing official, were assigned to the next new candidate. The suggestion, therefore, presented itself that were these uniforms formerly worn by tuberculous men capable of transmitting the disease to the next wearer. The author then: with a view to investigating the possibility of this theory, conducted a series of experiments. Uniforms were secured, their pockets removed and labelled; they were then washed, and the resulting washings were placed in a centrifugal machine until a sediment was obtained; this sediment was diluted and injected into sixteen guinea pigs; seven of these died from acute septic symptoms; while of the remainder, five recovered, but two of these subsequently died of tuberculosis. These facts are decidedly of importance, and the moral to which they point is self-evident. They clearly show that not only the personal clothing, but the bed-clothing of all persons dying of tuberculosis should be either effectually sterilised and washed or destroyed.

H.R.H. The Prince of Wales.

THE Prince of Wales in again honouring a Hunterian Orator by being present at the oration at the Royal College of Surgeons (England) last week, paid a gracious tribute to the surgical profession in this country, which was inspired no doubt by the desire to show some appreciation for the success with which the treatment of his fractured patella was carried out. It is, perhaps, quite true that His Royal Highness owes a good deal to the profession of medicine, but it is also equally true that the Prince, with his unfailing tactfulness, is never backward in making use of a favourable opportunity of showing his indebtedness. In view, however, of the repeated honours which he has conferred upon the Royal College of Surgeons by attending to listen to the Hunterian Orations the idea suggests itself that the College might follow the

lead of the Royal College of Physicians and offer for His Royal Highness's acceptance an Honorary Fellowship of the College. The Prince would then possess, in keeping with the present requirements of the profession, a double qualification-conferred by the conjoint Colleges. At present he is only qualified to practise medicine as a Fellow of the Royal College of Physicians; surely, therefore, the least that the College of Surgeons can do is to offer to make him an Honorary F.R.C.S., and perhaps, entitle him, should he so wish it, to be placed upon the Medical Register. We trust that for the honour of the College of Surgeons, the Council of the College will lose no time in taking the necessary steps to enable them to offer an Honorary Fellowship of the College to His Royal Highness.

President Kruger as a Patient.

THE presence of skilled, accomplished English practitioners in Johannesburg, some of whom are well known in the profession, does not seem to have had much civilising influence upon the President of the South African Republic. This worthy official, it is stated, has a rooted antipathy to medical men, which he is not slow to manifest. He has for some time been suffering from marked eversion of the lower lids and chronic conjunctivitis, but nothing will induce him to submit to the surgical measures necessary for the relief of the defect. Whenever he is prevailed upon to see a surgeon as to his condition, and the latter points out the relief which an operation would afford him, he at once directs the surgeon to leave his presence. The last medical man to give him this advice was a German, so it cannot be said that his refusal to be operated upon is determined by any political sympathies. After all President Kruger is setting a bad example to his own countrymen in the Republic. Moreover, he is probably losing a golden opportunity of acquiring a large measure of popularity and sympathy which the brave submission to a small operation would be likely to achieve for him. Upon the whole, then, on political, social, and personal grounds the President should accept the advice of his surgeons, and be cured of his distressing malady.

Prison Diet.

AT last the powers that be have decided upon the revision of prison dietaries, and we may hope that in future prisoners will be fed on a scale more worthy of a humane and scientific age. Hitherto prisoners have been underfed and overworked in a manner that turns them out after their term of imprisonment, be that short or long, so half-starved and weak that their chance of doing any honest work is reduced to a vanishing point. In this treatment the prison administration of this country is consistent, for the reform or rescue of the criminal appears not to enter into their calculations. Their main object seems to be to render the penal side of incarceration terrible by goading with an iron discipline the prisoner whose moral faculties have shared the degeneration of tissue entailed by what is

virtually chronic starvation. We do not advocate rose-water and eider-down for hardened offenders, but for many years we have protested against a system that imposes savage and unmeaning punishments for trifling offences against dis ipline, and which punishes a man by depriving him of food. The latter proceeding is illogical in the extreme, seeing that the brain is one of the first organs to suffer from damage to general nutrition. We hope to deal at length with this most important matter in an early issue.

Scarcity of Glycerinated Lymph.

MR. CHAPLIN has intimated that the demand for glycerinated calf lymph for vaccination, as supplied by the Local Government Board, is exceeding the supply, and steps have had to be taken in order to increase considerably the facilities for its preparation. It is also stated that, in addition to the public vaccinators, private practitioners are applying to the Board for the lymph, but in the latter case it has not been found possible to satisfy their requirements. Sir William Priestly has since pointed out to Mr. Chaplin that medical men would be glad to pay for the Board's lymph if it cou'd be supplied to them. Hitherto the lymph has been given without any payment being required. But it is clear that it would be an advantage to the Board to accept payment for their commodity, for in such a case they would be enabled to increase the means of its production. Mr. Chaplin has the matter under his consideration.

The Chloroform Bogey.

POPULAR ideas concerning the ease and rapidity with which unconsciousness can be induced by means of chloroform are curiously wide of the mark, hence the ludicrous statements that find their way into the press and into novels written by persons who have not taken the trouble to "verify their references." Last week the daily press related in all seriousness the story of an attempt to narcotise a traveller on a French railway by means of chloroform projected into the compartment through an aperture drilled for the purpose. If the anecdote be authentic the attempt merely proves profound ignorance on the part of the would-be miscreant of this particular method of anæsthetisation. Apart from the fact that it would take a prodigious quantity of chloroform to produce any appreciable effect unless held in close proximity to the mouth and nose, it is highly improbable that a sleeping person could be anæsthetised without being awakened, the olfactory nerve remaining active even during sleep. In the drama and in novels the rapidity with which chloroform narcosis is induced is a very conspicuous feature. Authors appear to be under the impression that it is sufficient to wave a handkerchief sprinkled with the drug in front of the victim's face during a brief space of time for the latter to sink, without resistance, into a limp, unconscious mass of an expert anæsthetist, justified by the patient's officer if he had to ascertain the circumstances of the

consent, it takes from five to ten minutes todetermine loss of consciousness, and that even then there is usually a stage of more or less violent excitement, it is obvious that, short of an overwhelming display of physical force, it would be next to impossible to narcotise an unwilling victim. The odour of chloroform is so pronounced and unusual, and the first effects on the organism are so singular, that its unsuspected inhalation is altogether incredible. In view of the fact that in spite of the precautions with which the law hedges in the sale of this drug, it can be obtained with tolerable facility by the exercise of a little patience and ingenuity, it will comfort the public to learn that its effects are not characterised by the fulminating rapidity with which they are popularly credited.

Alcohol in the Profession.

IT must ever be a matter for painful surprise that medical men, who cannot but be cognisant of the terrible and inevitable effects of excessive indulgencein alcohol, should themselves so often fall victims to this degrading habit. In some, no doubt, the habit is the legacy of irregular student life, but in the majority of cases drink seems to be resorted to for the purpose of combating the monotony and fatigue of daily practice. When to these factors is added the depressing sensation of failure, the temptation to see ephemeral comfort in alcoholic stimulation is too strong to be withstood by men of weak moral fibre. As one might expect it is especially in the lower walks of the profession that this form of indulgence is most prevalent. The habit is sometimes, no doubt, the cause of failure in practice, in others, the result of it. but however this may be, the lamentable fact remains that there is ample scope for medical temperance associations. The evil is unfortunately not confined to the victims whose influence on their patients in regard to the use of alcohol can hardly be other than disastrous. The time may come when notorious addiction to alcohol will be regarded as a sufficient reason for inhibiting the peccant member from the practice of his profession, and no one can deny the grave risks to the public which such a habit mustentail. Medical men and ministers of religion occupy positions of great moral responsibility, and they owe it to their patients and flocks to set a good examplein this, as in sundry other, respects.

A Niggardly Board of Guardians.

A POINT of some importance was recently elicited at the Crediton County Court under rather peculiar circumstances. Dr. Haycroft, a Poor-law medical officer, attended a woman during labour in conformity with an order to that effect served upon him by one of the overseers. The guardians, however, declined to pay his fee of a paltry half-guinea on the ground that, as the woman's husband was not destitute, he, and not they, was liable for the amount. Judge Woodfall appraised the behaviour of these niggardly guardians at its proper estimate, observing Considering that in the hands that it would be an intolerable burden on the medical

people he was called upon to attend, adding that the Poor-law did not contemplate the administration of medical relief "in any such grinding spirit." As leave to appeal was asked for and granted, it looks as if these mean-spirited officials intended to challenge his ruling, but if so, we trust that the general body of Poor-law medical officers will rally round Dr. Haycroft, who is fighting their battle.

The Irish Collegiate Preliminary Examination.

FOR some years past the General Medical Council has sought to crush out of existence the preliminary examination held conjointly by the Royal Colleges of Physicians and Surgeons, Ireland, the obvious purpose being to clear the ground of all competition with the Universities, no reason being assigned for the wished-for extinction. These colleges, while both expressing and demonstrating their willingness to raise the standard as high as the General Medical Council might desire, resisted annihilation on the grounds that no other examination is open, in Ireland, to the average medical student. Inasmuch as (a) The recognisable examinations of Dublin University involve a payment of £15 and are, in some cases, inferior in standard. (b) Those of the Royal University are two in number, and with an interval of a year. Under these circumstances, it was suggested by the Irish Colleges that the examinations of the Intermediate Education Board, now in course of reorganisation by a Commission, might supply the want if three objections to these examinations could be overcome. The objections are these: -1. That they are held in June, which does not suit the students annus medicus. 2. That the age for the Junior Grade examination is too early for such student. 3. That the extreme age limit for any of the Grades is only eighteen years, and that a student who had not passed by that time would be excluded for ever. 4. That, in any case, a student would have to lose an entire year if he failed to pass at the first attempt. It was suggested that the Intermediate Board might make special arrangement to overcome these difficulties, and, to that end, the colleges, represented by Dr. Atthill, for the College of Physicians, and Sir William Thomson, for the College of Surgeons, testified before the Commission last week. They placed these points very clearly and, apparently, with considerable effect, and we should hope that a modus vivendi may be arrived at.

The Livingstone College.

THE fifth annual report of this useful Institution was read at a meeting of the subscribers and supporters last week. It appears to be doing an excellent work, and is worthily deserving of the cordial assistance of all the missionary societies. By means of the education supplied by the college, not only are missionaries the better able to look after their own health, but many opportunities are afforded them to using their knowledge to advantage upon others.

Ancient Burial Vaults.

In most of our great towns there exist vast collections of coffins piled up in the crypts of churches, a ghastly bequeathal from the times when our forefathers had not realised the elements of wholesome environment. Such burial vaults still abound in the metropolis, where the size of the population and the lack of proper cemeteries made them in former days especially convenient and lucrative. Last week no less than 200 coffins were discovered stowed away beneath a Friends' mission house at Limehouse, the date of the latest burial being 1856. The Home Office has taken the matter in hand, and it is to be hoped that their efforts will be more speedily successful than in a very similar case of the Parish of St. George the Martyr, Southwark. Last summer (as readers may remember) London was startled with the news that some 1,500 to 2,000 coffins were lying in the vaults beneath the church of that ancient parish. After sundry official proceedings an order for removal was sent to the vestry by the Home Office. Six months later no action has been taken by the local authorities, and, if we are to believe the assertion of the newspapers of the district, the official notice actually lay unopened for four out of the six months. There can be little doubt that a systematic search would reveal not a few such undesirable burial places, and we must thank the Church of England Burial Reform Society for persistently having, for years past, drawn attention to this danger to health. In these cases we think the Home Office would do well to cremate the whole of the remains, or if their powers do not extend so far, to apply to Parliament for the necessary authority.

A Classical Suicide.

A SOMEWHAT curious case of suicide has been recently investigated at C:oydon. The man seems from the evidence to have gathered hemlock, wherefrom he distilled the poison that formed his draught. This proceeding was possibly suggested to him by a perusal of ancient history, when poisoning by conium was a recognised means of inflicting death, whether penal or suicidal. The paralytic properties of the plant conium appear to have been recognised at the dawn of civilisation and probably a long time before that epoch, as we find some of the most degraded aboriginal tribes possessed of considerable toxicological lore. The personal account of the symptoms of conium bequeathed to posterity by the dying Socrates stamps him as a master of accurate observation. The "death-cup" of the ancient Greeks, among whom suicide was common, consisted mainly of the juices of a species of hemlock. A similar remark is true of the ancient Romans, with whom, indeed, some authorities maintain the morbid and degenerate fashion originated. It is somewhat noteworthy, by the way, that, notwithstanding the advances of modern chemistry and pharmacy, scientists have not yet discovered a physiological antidote to the poison of hemlock.

The Spread of Venereal Diseases.

THERE is no greater anomaly in the whole of our curiously mixed social administration than the way in which venereal diseases are allowed to flourish un-From a logical point of view the exact position of that class of maladies is clear enough. They form a well-defined and deadly group of the great family of communicable diseases. As regards many of the specific infectious diseases, as a community we have taken up a stong attitude, and have assumed the right of control over the individual in the interests of the many. The results of that action are recorded in the brilliant annals of preventive medicine. Nevertheless, at the end of the 19th century we leave severely alone the most loathsome and insidious of communicable diseases. Some thirty years ago an attempt was mide to deal with the question by the passing of the Contagious Diseases Act. That measure, however, was so imperfect that the repeal that overtook it in 1886 might almost have been foretold. It applied, for instance, to certain towns only, it controlled one sex alone, and it placed the possibility of terrible abuses in the hands of the police. Yet Great Britain enforces a modified Act in India, and it may well be asked in the name of reason and common sense why the same thing should not be done at home. The somer the whole question of venereal disease is treated purely and simply as a health matter, and quite apart from its moral aspects, the better for the national welfare.

The Forthcoming International Gynaecological Congress.

WE are asked by the Honorary Secretary of the International Congress of Gynæcology and Obstetrics, which is to be held at Amsterdam from the 8th to the 12th August, to publish the following latest arrangements:—

The questions for discussion are as follows: -

- 1. The surgical treatment of fibro myoma.
- The relative value of antisepsis and improved technique for the actual results in Gynæcological Surgery.
- 3. The influence of posture on the form and dimensions of the pelvis.
- 4. The indication for Cæsarian section compared to that for symphyseotomy, craniotomy and premature induction of labour.

Among those who have ccusented to take part in these discussions are, Messrs. Doyen, Howard, Kelly, and Schauta, who will treat the first question; Messrs. Bumm, Richelot, and Lawson Tait, the second: Messrs. Bonnaire, Pinzani, and Walcher, the third; and Messrs. Leopold, Pinard, and Pestalozza, The reports with their translations in the fourth. the official languages will be sent to all the members a month before the opening of the Congress. As regards private communications, preference will be given to those bearing upon the above-mentioned leading questions. Sufficient time will also be allowed for any demonstrations kindly afforded by the members. The official languages are, English,

French, German, and Italian. The subscription for membership is one guinea. Subscription forms and further particulars may be obtained from the Hon-Secretary for Greet Britain and Ireland, Dr. Arthur Giles, 37 Queen Anne Street, London.

Earth-Eating.

THE Société Anthropologique of Vienna reports to us curious information of the geophagic or eartheating habit. This custom exists in many tropical countries. It is especially practised by negroes and Indians, but exceptionally in Europe. Lasch quotes the case of workmen employed on an English racecourse, who at all times spread clay on their bread and eat it with a relish. In Persia certain earths are considered by gourmets a great dainty. In the Archipelago the people buy "ampho" earth in provision shops. In China, New Caledonia, and New Guinea geophagy is much practised. Humboldt observed it in America and Lasch remarked that among savages (especially pregnant women) earth was much used, the latter considered it assisted them in their confinements. In Guatemala it is used in connection with superstition, and in the course of religious ceremonies the faithful may be observed devouring statuettes of clay, with an air of profound devotion. From this barbarous practice results consumption, anæmia, and inflammation of the liver.

The Epidemic of Influenza.

The epidemic of influenza is not confined to the metropolis. From various parts of the country we receive reports of its prevalence. Among the men employed at the railway works at Crewe, for example, hundreds are reported to be incapacitated for work, and some difficulty in the traffic department has been experienced from the same cause. A similar state of things prevails in Glasgow, where business is dislocated by the large number of absentees. As we predicted a few days since, the resources of the various provident funds and slate clubs have a heavy strain put upon them by the unforeseen prevalence of sickness.

A Midwife Censured.

MRS. AVENELL, æt. 71, a Walthamstow midwife, who claimed to possess a "diploma" from the Obstetrical Society, and to have successfully passed the curriculum of the "Ladies' Medical College," whatever that may be, with honours, has been severely censured by a coroner's jury for her conduct in connection with a labour which she had attended, the patient having succumbed to septic complications, the result of want of cleanliness and negle:t. The censure will doubtless have the desired effect, in that it will deprive this careless nurse of further opportunities of doing mischief.

SURGEON A. R. BANKART, H.M.S. 'Surprise,' who was in attendance upon his Royal Highness the late Hereditary Prince of Saxe-Coourg and Gotha during his last illness, had the honour of being received hy Her Majesty at Windsor last week.

The Royal Army Medical Service.

It must be a source of unmitigated satisfaction to the military authorities to find that the measures of reform so reluctantly conceded by them have had for effect to restore the Army Medical Service to its erstwhile popularity. At the recent examinations there were upwards of seventy candidates for twenty-four vacancies, so that, for the first time for some years they were competitive in fact as well as in name. Unfortunately the evil effects of the last few years will not at once disappear, and it will take a considerable time for this department of the Service to "level up." None the less we congratulate "my military advisers" on having restored order out of chaos, and on having averted what at one time threatened to be a deadlock.

Food Adulteration in America.

It has been estimated that food adulteration takes place in America to the extent of £140,000,000 per annum. In other words, the people of the United States are swindled out of this amount by dishonest tradesmen. The sum seems an enormous one, and it is remarkable that such a practical people as the Americans are should allow themselves to be so victimised. The necessity, however, for dealing with the evil has, it appears, at last become palpable, so much so that two Bills for the prevention of the adulteration of food and drugs have just been introduced into Congress. Perhaps Congress might learn something from the laws in force in this country upon the subject of food adulteration. But there is no saying.

THE author so widely known as "Cavendish," in private life Mr. Henry Jones, whose death took place a few days since, was himself a medical man, and the son of Mr. Henry W. Jones, also a medical practitioner, of Soho Square. Mr. Henry Jones took his M.R.C.S. in 1852, and subsequently became a member of the Society of Apothecaries. He ceased to practise in 1869, but had long before achieved the position of an unquestionable authority in all matters appertaining to card-playing. His numerous works, all written under the nom de plume "Cavendish," still hold their own in all English-speaking countries. It is a curious fact that his father, who was very fond of a rubber at whist, acquired the habit of settling dis putes by referring to "Cavendish," years before he became aware that the author was his own son.

An Order in Council will shortly be issued for the increase of a number of medical officers for the Royal Navy. The establishment is up to its limits at the present moment, but it is determined that these shall be still further increased in order to provide for eventualities.

COLONEL J. A. CLERY, R.A.M.C., has been se'ected for the appointment of Principal Medical Officer to the Woolwich and Thames district, in succession to Colonel Ferguson, who retires from the service next month.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

INFLUENZA IN EDINBURGH.—The citizens of Edinburgh are suffering at present from a wide-spread epidemic of influenza, luckily, as yet, in a not very dangerous form. As far as can be ascertained, both from the cases seen in hospital and outside, no specially marked type, such as that which was characteristic of the much milder epidemic of last spring, viz, the gastrointestinal type, can be said to be shown in its victims; it chiefly appears in a simple pyrexia, more or less pronounced, with or without arthritic pains, and culminating in exceedingly profuse perspiration. Moderately acute nervous sequelæ, however, are apparently more common than in several of the epidemics of recent years.

EDINBURGH HOSPITAL REPORTS.—The members of the medical staffs of the various infirmaries and hospitals in Edinburgh have at length decided to proceed with the publication of the Edinburgh Hospital Reports. Five volumes have been published since 1891, but the existing arrangement having expired at the end of five years, and difficuties having arisen in retheir continuance, the whole question has been submitted de novo to the medical staffs, and reorganised upon a wider basis. The Royal Infirmary, Royal Hospital for Sick Children, the City Fever Hospital, Leith Hospital, Edinburgh Royal Asylum, and the Deaconess, Victoria, and Chalmer's Hospitals have all been invited to collaborate, and all of them, we believe, have promised to do so.

GLASGOW FOG AND THE DEATH-RATE.—On account of the dense fog in Glasgow a few days ago the death rate made a leap upwards to 35 per 1,000 of the population, thus placing Glasgow in the unenviable position of having the largest death-rate of any town or city in the United Kingdom. This high mortality has not been reached since the winter of five years ago, when the frost and fog were intense. Even then the same suffocating and throttling effect was not experienced as on the present occasion, when several instances of giddiness and vomiting in the street came under our immediate notice. Whether the smoke and soot-laden atmosphere was charged with a larger quantity of poisonous gases, or that the influenza bacilli were more numerous as well as ponderous, is, perhaps, difficult to decide, yet it is a fact that since the fog passed off influenza has been increasingly prevalent in the city, so much so that in the police-force alone there are at least 100 men off duty.

PRINCIPAL STORY "MEANS BUSINESS"—The late Professor Coats remarked in a letter which, strange to say, was publicly read on the evening preceding his death "Principal Story means business." It is noticed that the Principal is taking the very sensible step of familiarising himself with all the details of university affairs. More than one classroom having been lately visited by him and, as graphically put, heroically sitting out the lecture; and now, by means of an "At Home," he is about to form the personal acquaintance of the lecturers, assistants, examiners, office staff, and librarians. This evidence of interest displayed by the Principal or Academic head is greatly appreciated by the officials generally.

Literature.

LENNOX BROWNE ON THE THROAT AND NOSE. (α)

Mr. Lennox Browne deserves the thanks of the profession for this new edition of his book. It is practically a new work, and some of the very best parts of the book are those that he has now added to it. Both the text and the illustrations are full of interest, and it would be hard to find a more thorough or more instructive account of all the facts of laryngeal surgery. The arrangement of the whole subject is well thought out, and

(a) "The Throat and No-e, and their Diseases." By Lennox Browne, F.R.C.S. E. Fifth Edition. Bailliere, Tindall and Cox. London. 1899. Pp. 967. With 550 Illustrations in Colour. Price 31s. 6d.

from beginning to end the book is clear, practical, and full of experience. The numerous cases that he quotes are well selected and well described, and the book is enriched with an immense number of admirable coloured plates. His illustrations of the diseases of the larynx are so good that they stand the severe test that should be applied to all such pictures—that one should hold them upside down, and look at them with a laryngeal mirror, and see whether they stand out like the living structures. Altogether, the book is excellent, and forms a most notable addition to the literature of

There is first a very careful and comprehensive account of the anatomy and physiology of the upper air passages, including the microscopic structure of the different tissues. Then comes a well-written set of rules how to use the laryngoscope and examine the nasal passages In all this part of the book, there is hardly a word that can be criticised; unless it be the statement (p. 119) that a wide naso-pharynx is more likely to be diseased than a narrow one: "the wider the distance between soft palate and pharynx, the more surely one may expect, on examination, to find post-nasal trouble." The chapters that come n-xt, on the general signs, treatment and pathology of the diseases of the throat, are very good; and in all of them we find only two points for criticism. One is that Mr. Lennox Browne seems to us to over-rate the importance of the lingual tonsil and its veins; the other is his statement that spasm of the pharyngeal muscles "is liable, if neglected, to lead to true stricture of a practically, if not actually, malignant nature.

His account of the diseases of the tonsils is excellent, especially the rules of treatment. For simple acute ton-illitis, he recommends that the inflamed surface should be painted with equal parts of guaiacol and almond oil. He does not, we think, take such a hopeful view as he might of operative interference in cases of malignant disease of the tonsil. The chapter on adenoids is one of the best parts of the book, and we note with approval that he has given up the use of the artificial nail in favour of the forceps or the curette. We doubt whether he is justified in putting stammering among the defects that may be cured by the removal of adenoids: it does not seem likely that the operation could put an end to any real impediment of speech.

The chapters on laryngitis (pp. 434-609) are of great value, especially for all that he says about the singing voice. The other chapters on the laryngeal diseases raise two questions which Mr. Lennox Browne has already raised in debate—the exact measure of the advantages given by the antitoxin treatment of diphtheria, and his belief that a benign growth in the larynx may be irritated into malignancy by surgical treatment. On the first of these questions he writes with great care and moderation; on the second, we think he ought to give up his position altogether, and certainly he yields most of the ground.

His account of nasal diseases evinces a perfect grasp of the subject, and is by no means the least valuable part of the book. Finally, there is a very good short chapter on those aural troubles that are most associated with naso-pharyngeal disease; and a good list of formulæ.

The whole book is worthy of praise, both the text and the whole book is worthy or praise, both the text and the plates, the printers' and publishers' work keeping pace with the author's in point of excellence. The special chapters contributed by Mr. Mayo Collier, Dr. Cagney, and Mr. Wingrave add much to its thoroughness. Here and there a captious critic may find a fault of style—some unnecessary claim of priority in work, or some horrible half-treek, half-Latin word. But it is, on the whole, a very fine piece of work, careful, complete, and thoroughly practical, and we doubt whether its equal is to be found in the English or any other language.

SQUIRE'S COMPANION TO THE BRITISH PHARMACOPŒIA (a).

It is but four short years since the sixteenth edition of this indispensable work of reference was published, but many and important changes have taken place since

(a) "Companion to the British Pharmacopaia." (1 ast Rdition.)
By Peter Fquire. 17th Edition. Revised by Peter Wyatt Squire,
P.L.S., F.C.S. London: J. and A. Churchill. 1899. Price 12s. 6d.;

Not only is additional information available then respecting drugs with which use has already made us familiar, but various new drugs and compounds have been introduced into therapeutics on approval, and claim our attention. The present edition has been claim our attention. The present entition has been brought well up to date, containing, as it does, references as recent as January of this year. Among the more recent additions to the unofficial repertory of contemporaneous therapeutics, are the following: Heroin. peronine, ephedrines, hydrochloride, mydrin, tartrate of piperidine, &c. How many of these will be retained after being rubbed through the sieve of experience, time alone There are quite a number of products introwill show. duced as substitutes for cocaine, and some of them may possibly secure a share of popularity, notably eucaine, the chemical name whereof takes a whole line all to itself. Under the head of silver also we are treated to a large number of new compounds, most of them intended for the treatment of urethral troubles, special advantages being claimed for each. Considerable space is devoted to the pharmaceutical peculiarities of creosote and guaiacol, which, with their compounds, appear to belong to the select group of remedial agents capable of really rendering service in the treatment of tuberculosis.

In order to facilitate reference, the paragraphs dealing with solubility, therapeutical properties, prescribing notes, and list of official preparations have been arranged on a novel plan, so that all the information required under the respective headings can be seen at a glance. In the task of embodying the results of the most recent researches, certain articles have had to be virtually rewritten, as, for example, those on atropine and its salts. digitalis, ipecacuanha, jaborandi, opium, nitrate and hydrochloride of pilocarpine, sulphate of quinine, and

last, but not least, the thyroid gland.

The notes, interspersed here and there, on the definitions contained in the new Pharmacopeia afford proof of original observation, and we commend them to the editors of the efficial compilation. In respect of benzoic acid, for instance, the Pharmacopæia defines the acid as obtained from benzoin by sublimation, which strictly speaking is the "Resin-Sublimed Acid; it possesses a strong empyreumatic odour. It is stated, moreover, that "benzoic acid is odourless when quite pure, but when obtained from benzoin possesses an aromatic odour," thereby inferring that the acid generally used would not be obtained from benzoin. It would have been more correct to have stated that the acid is obtained from benzoin by precipitation and subsequent sublimation, such an acid although obtained from benzoin does not possess the odour of the drug. Then, again, in regard to bismuth carbonate, this, says the editor of the "Companion" is an instance of the disadvantage attaching to the new method introduced into the B.P. of grouping the characteristic reactions. It has been very pertinently asked whether iron, arsenic, lead, tellurium, selenium, and magnesium are all equally objectionable ? Under bismuthi salicylas the editor states "we have not yet seen a sample which would pass the ferric chloride test, also there is a slight discrepancy between the figures given for bismuth sulphide and bismuth oxide. Although Mr. David Howard called attention to the inaccuracy of the formula given for bismuthi subnitras in B.P. 1:85, the error is repeated in B.P. 1898. It is also at variance with the official test which requires that it should yield 84 p.c. of bismuth sulphide." Avis a qui de droit!

It is comforting to be assured that chloroform sp. gr. 1.497 is not as liable to change on keeping as is generally supposed. We may particularly call the attention of our readers to the radical changes in the formula for the preparation of tinctura chloroformi et morphinæ composita, which is now official in place of the tinctura chloroformi et morphinæ of B.P. 1885.

Another note of special interest bears on the great change with regard to eucalyptus oil. Eucalypti oleum as defined officially is the oil distilled from the fresh leaves of eucalyptus globulus, and other species of eucalyptus, and there is nothing to call attention to the fact that the oil from a particular species (eucalyptus amygdalina), which has been official since 1885, is now excluded by the official tests. This, after all, is of more

Digitized by GOOGLE

interest to chemists than to medical men. Respecting hyoscine hydrobromidum the editor asks whether the compilers of the test given for this salt have ever met with a salt in commerce of the melting point given (193 to 194 degs.).

It is pointed out that the hydrochloride of pilocarpine is official in most other pharmacopoeias, probably because it more readily admits of purification than the nitrate, commercial samples of which vary in their melting point.

The Pepsin test, remarks the editor, is a half-hearted copy of the U.S.P., but omits important particulars relating to the stirring, and B.P. directs the almost microscopic quantity, $r_{\rm s}^{\rm t}$ th of a grain, to be weighed out for the test, instead of employing a measured quantity of a solution of definite strength. Under lithium carbonate, lysidine, piperazine, and piperadine tartrate, references are given to the latest work (by Luff) as to the action of these substances on sodium biurate. Large numbers of notes occur under menthæ piperitæ oleum, and medicinal

properties of menthol enlarged.

In conclusion we may congratulate the editor upon having achieved the task of revision of this impatiently awaited work with so little delay. It is a "Companion" in the best literary sense of the term, and generations of practitioners and pharmacists have learned to appreciate its accuracy, its comprehensiveness, and the admirable arrangement of its heterogeneous contents whereby reference is made easy. The work has now reached a degree of perfection which defies constructive criticism, and the welcome which has been extended to its predecessors will certainly be accorded to the seventeenth of

Literary Aotes and Gossip.

Dr. F. J. Webb, a Manchester practitioner, has just published a work which graphically portra's many features of medical student life, and particularly illustrates the trials and disappointments of practice. The novel has been well received. "Harry Ingelby, Surgeon," is the title of the work.

Ruskin at eighty has been photographed in his study by the well-known photographer, Frederick Hollyer. reproduction of this photo is given, by permission, in the "Leisure Hour" for February. Old Alleynians will be pleased to see in the same magazine their popular Latin school-song, written by Dr. Welldon when headmaster of Dulwick College. Dulwich College. ***

MESSRS. LONGMANS inform us that a considerable portion of the work of revisal necessary in the preparation of a fourth edition of "Coats' Manual of Pathology" had been already accomplished by Professor Coats immediately preceding his death; and in response to the author's expressed wish the editorial duties have now been assumed by Dr. Lewis R. Sutherland, Senior Assistant to the late Professor of Pathology, University of Glasgow. It is expected that the work will be ready for publication in the early autumn.

THE "Text-Book of Zoology," by Messrs. Wells and Davies forms part of "The University Tutorial Series," and it is in reality a revised and enlarged edition of a work published five years ago, now before us. What with alterations in the schedules of requirements of examining boards, and with the progress of knowledge, this new edition does not come any too soon. The authors' experience of actual teaching has been turned to good account, and all trace of ambiguity has been eliminated from the text, which is copiously illustrated by diagrams specially drawn for the book by Mrs. Davies. What is known as the "type system" of imparting an introductory knowledge of natural history sciences has been adopted, but every endeavour has been made to obviate the drawbacks associated with the too exclusive restriction of the attention to isolated species. Though compact, this work deals very comprehensively with the subject; the text is lucid and is clearly printed, whi e the diagrams reflect great credit on their delineator.

THE "Handbook of Obstetric Nursing," by Dr. F. W. N. Haultain and Dr. J. Haig-Ferguson (Edinburgh: J. Pentland), primarily destined for the instruction of obstetric nurses, is an admirable compilation. It errs, if anything, in the direction of over-comprehensiveness, for a medical student who had, even approximately, mastered its contents, would probably pass any examination on the subject with flying colours. It is liberally illustrated, and the title page is faced with a full-page coloured diagrammatic drawing of a woman at full-time preg-Apart from the usual chapters on anatomy, pregnancy, and labour, there is an excellent expose of antiseptic principles, and much space is also devoted to eclampsia, and other complications of labour and the puerperium. The chapter on the management of the child is worthy of praise, and the volume closes with an appendix setting forth the duties and responsibilities of the midwife, followed by a glossary of medical terms.

DR. PORTER MATHEW'S "Clinical Observations ,000 Obstetric Cases" abstracted from his thesis for M.D. (Cantab.), is a well-digested synopsis of the results of the careful scrutiny of a large number of obstetrical records justified by an unusually large personal experience. The author's remarks are characterised by much sound common sense, and command respect even when they do not conform to accepted views. He points out, for example, that the presenting part is usually much lower in primiparæ than in multiparæ before the onset of labour, owing to the greater abdominal tension in the former. He reminds us too, that the ear is a valuable guide to diagnosis in doubtfut vertex presentations, a fact not alluded to in most text-books. We learn that in 1,200 cases, albuminuria was present in 20 per cent., the amount exceeding 1-20 in over 4 per cent, and primi-paræ are five times as liable to this complication as multiparæ. There are many other valuable hints which will repay perusal by those interested in obstetric practice, and the work, brief though it may be, stamps the author as an original and painstaking observer " dignus intrare."

THE "Strange Stories of the Hospitals," by Frank Aubrey, is a book with a purpose. Its kindly object is sufficient to render it worth of consideration. It is dedicated to the Council of the Hospital Saturday Fund, and all profits arising from the sale of it are to be placed at the disposal of the managers. The author's intention is to bring before the public what he terms "The Picturesque and Romantic Side of Hospital Work" in the hope that the interest excited by this novel point of view may be the means of increasing subscriptions to medical charities. Of the stories themselves there is little to say. They are short and simple, and some of them are certainly strange enough to warrant the old proverb with regard to truth and fiction. Such, for instance, is the tale of the "Gold Idol," in which we read of the terrible misfortunes that befell the successive owners of a little golden figure stolen by some South American explorers. If these tales excite an interest in hospitals and their motley inhabitants, the labour of writing them will not have been thrown away.

THE book by Wirtzung, respecting which a correspondent asks our opinion, is probably the English translation of Jacob Mason, published in London by E. Ballifant, in 1598, of Wirtzung's Praxis Medicinæ Universalis. "A generall practise of physicke; wherein are contained all inward and cuttured practice." inward and outward parts of the body, with all the accidents and infirmaties that are incident unto them, even from the crowne of the head to the sole of the foote; also by what meanes (with the helpe of God) they may be remedied; very meète and profitable, not only for all phisitions, chirurgeons, apothecaries, and mid-wives, but for all other estates whatsoever, the like whereof as yet in English hath not been published. Compiled and written in the German tongue, and now transl. into English, in divers places corrected, and with many additions illustrated and augmented, by Jacob Masen" Wirtzung was born in 1500, and died in 1571. His book went through seven German editions. To the medical archæologist it is interesting as showing the accepted theories of medical practice in the sixteenth century. Its market value would be about 10s. 6d.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list: -

CASSELL AND Co. (London).

Year-Book of Treatment for 1899. By Various Contributors. Pp. 473. Price 7s. 6d.

J. AND A. CHURCHILL (London).

A Manual of Diseases of the Nervous System. Vol. I. The Nerves and Spinal Cord. By Sir W. R. Gowers, M.D., F.R.S., and James Taylor, M.D., F.R.C.P. Third Edition. Pp. 692. Price 15a

H. K. Lewis (London).

The Liverpool Medico-Chirurgical Journal. Vol. XXXVI. Pp. 194. Price 3s. 6d.

LONGMANS, GREEN, AND Co. (London).

Elementary Physiology. By Benjamin Moore, M.A. Pp. 295. Price 3s. 6d.

OLIVER AND BOYD (Edinburgh).

Notes on Surgery for Nurses. By Joseph Bell, M.D., F.R.C.S.Ed. Pp. 194. Price 2s. 6d.

PATTER AND CLARKE (London).

King's American Dispensatory. New Edition. Rewritten and enlarged by Drs. Harvey W. Felter and John Uri Lloyd. Two vols., 950 pp. Price 4.50 dols. per vol.

Young J. Pentland (Edinburgh).

The Edinburgh Medical Journal. New Series. Vol. IV. Edited by G. A. Gibsou, M.D., F.R.C.P.Ed. Pp. 600.

THE SCIENTIFIC PRESS, LIMITED (London).

The Nursing Profession: How and Where to Train. By Sir Henry Burdett, K.C.B. Pp. 241. Price 2s.

SMITH, ELDER AND Co. (London).

St. Bartholomew's Hospital Reports. Vol. XXXIV. Edited by Norman Moore, M.D., and D'Arcy Power, F.R.C.S.

THE UNION STEAMSHIP COMPANY (London).

South Africa as a Health Resort, especially for Consumptive Invalids. By Arthur Fuller, M.B., Ed., M.R.C.S.

J. WHITAKER AND SONS (London).

The Naval and Military Directory and Indian Army List for 1899. Pp. 656. Price 5s.

THE DEATH OF PRESIDENT FAURE.

From information which we have been enabled to glean from authoris: d sources, it appears that the sudden death of M. Felix Faure did not come upon his medical advisers altogether as a surprise. Only last year, in the course of an examination for the purpose of ascertaining the exact nature of a painful affection of the left knee, it was discovered that the heart was notably enlarged, and on consultation, un'quivocal evidence was obtained of an atheromatous condition of the aorta, a form of degeneration the importance whereof is too well known to physicians to call for explanation. Some wasting of the muscles of the leg was noticed, but this promptly yielded to a course of massage and electricity and the limb ceased to cause any trouble. The existence of high arterial tension inspired feelings of apprehension in the minds of those upon whom devolved the responsibility of advising the distinguished patient, and these found official utterance on more than one occasion though, for good and obvious reasons, it was not thought desirable or necessary to take the public into their confidence. The first symptoms of the attack which ultimately proved fatal were suggestive rather of an impending attack of angina pectoris, great præcordial distress being complained of, with intense pallor and a tendency to syncope. Drs. Lannelongue and Bergeron, summoned in hot haste, almost at once remarked the gradual supervention of right facial paralysis, leading to distorsion of the features which was painfully evident school.

even when lying in state and this placed the diagnosis on a sure footing. The pulse was 74 per minute and regular, though with occasional intermittences. Respiration was normal and consciousness was retained. Soon, however, the tongue became paralysed in its turn, and after a brief period the paralysis extended down the left side of the body. It was evident in short that a vessel had ruptured in the neighbourhood of the upper part of the medulla, and it was not less evident that a fatal issue was virtually inevitable. This gloomy prognosis was rapidly confirmed by loss of consciousness, which gradually merged into coma, in which condition death supervened, only three hours and a half after the first malaise. No autopsy appears to have been made, or if so the details have not been made public.

THE LONDON UNIVERSITY.

A conference between representatives of the Government, the University, and the Imperial Institute will shortly be held to consider the proposal for a migration of the University to the latter Institute under authority of the Act of last session.

IDEAL SANITATION.

The aspirations of theoretic sanitarians (at least, those ideas which they are content to put forward for the present) have been formulated in a Bill introduced to the Commons by Sir Alfred Hickman and Sir Walter Foster. It provides that washerwomen shall furnish to the Medical Officer of Health lists of the owners of clothes which may be suspected of infection—that all infected persons shall cease business—and that books in public libraries shall be periodically disinfected. Also that cow-keepers shall notify the sources of supply of their milk, the persons to whom it may have been distributed, and all cases of infective disease in their servants, and, also, of tuberculosis anywhere.

PROFESSIONAL EXPURGATION OBSTRUCTED.

WE learn with regret that, probably, both the London and the Dublin Colleges of Physicians will decide to oppose the very necessary and reasonable proposal of the Medical Council that a misdoer who has been struck off the Register for "infamous conduct" shall not be allowed to persist in the use of his diplomas for illicit practice, as many such do. The Medical Council desires that it shall be declared that such use is illegal, and that the public shall be thus protected, but the oppressive dignity of these Colleges will not, it is feared, allow the proposal to be carried out lest some scintilla of their rights might be sacrificed. It would be a great pity that the Pontifical robe should be sullied for the good of the profession or the public.

MR. WILLIAM JOSEPH MYLES STARKIR, who succeeded Sir Thos. Moffett as President of the Queen's College, Galway, has been appointed Chief Commissioner of Education, and has thus opened the former office to competition.

In response to the Right Hon. Mr. Balfour's appeal for the endowment of Medical Research, Sir Frederick Wills has forwarded a cheque for £5,000 to the Treasurer of Guy's Hospital for work in this direction in the medical school.

Parliamentary Acws.

Foreign Milk.—In reply to Mr. Warner, Mr. Chaplin, President of the Local Government Board, stated that foreign milk as soon as imported is subject to the same treatment as English milk, but obviously the regulations which apply to dairies and cowsheds in this country, cannot, of course, apply to dairies and cowsheds abroad. The matter is, however, of comparatively small importance, because while the consumption of milk is estimated at 600,000,000 gallons a year, 60,000 gallons only were imported during the ten months ending in January last; and, according to the latest returns, the quantity is de-

creasing as compared with last year.

The Metropolitan Asylums Boards.—Mr. Chaplin, in reply to Mr. H. E. Kearley, said the Metropolitan Asylums Board were taking active steps to find suitable premises for invalid children. For children afflicted with ophthalmia two sites had been purchased, one on either side of the Thames, for buildings intended to accommodate 360 children. For children suffering from ringworm, negotiations were being made for the acquisition of the Sutton Schools. For children of defective intellect, managers had provided a home for twenty girls sent by the Guardians. Homes had been provided for co-valescents, one at Herne Bay for 134 children, and the other at Margate for 41. 289 children had been admitted to these homes. Another site had been purchased on the south coast on which to erect three houses to accommodate twenty-five children each. These arrangements would provide for all the children requiring seaside air.

The Plague.—In reply to Dr. Tauner, who asked the Secretary of State for India if there was any foundation for the report from Bombay of a plague panic from the southern Kolar goldfields, and what steps were being taken to prevent further loss of life, Lord G. Hamilton stated that the latest information received was that during the week ending Monday, February 13th, there were 12 plague seizures and 9 plague deaths in the Kolar district of Mysore. Nothing was said in that report as to any plague panic among the gold miners. The Mysore State, supported by the British Resident, and aided by the Government of India, he added, was sparing neither expense nor effort to combat the plague wherever it appears in Mysore territory.

Tuberculous Cattle.—Mr. Warner asked the First Lord of the Treasury whether he proposed to introduce any Bill for appointing Government inspectors to inspect and condemn cattle afflicted with tuberculosis, as uniform action all over the country was most desirable on this subject, and as one private Bill had been introduced by a corporation to give its own inspectors these powers outside the municipal boundaries. Mr. Long, who answered the question, said it was not the intention of the Government to appoint inspectors for the purpose suggested, and, as far as the legislation to which he referred was concerned, it was impossible to say what powers in this direction Parliament would grant to local authorities.

COMPANY PHARMACY IN IRBIAND.—A somewhat sympathetic reply was elicited from the Chief Secretary to the question, by Dr. Tanner, respecting unqualified traders who had been prosecuted for offences under the Irish Pharmacy Act, and, though convicted, were enabled immediately to extricate themselves from the penalties out of the Act, and pursue their illicit trade by turning themselves into a limited company. The Chief Secretary said that "the subject had been brought before him by the society, and would call for consideration whenever a general amendment Act for the whole kingdom is proposed," but he did not say when there was any chance of this.

Laboratory Aotes.

"HIPI" MUTTON ESSENCE.

WE have received from Messrs. George Nelson Dale and Co., of 14 Dowgate Hill, E.C., samples of "Pure Mutton Essence (Hipi Brand). The preparation is one which fulfils a distinct want, and as it compares very

favourably with similar preparations of beef, it will be the means of introducing a welcome relief to the monotonous dietary of the febrile patient. Our analysis gives the following results:—

Moisture Nitrogenous matter, inclu-	 ding gelatine		42·0 43·0
Mineral matters		•••	8·4 6·6
Non-nitrogenous extractiv	res	•••	0.0
			100:0

The mineral matter consists merely of phosphates. The fatty constituents of mutton are eliminated during the process of manufacture, and the composition of the extract justifies its claim to be considered as an article possessing a high dietetic value, especially as the proportion of merely stimulating principles is small compared with that of the really nutritive substances. The flavour is satisfactory, and the product is certainly one which merits a prominant place in invalid dietetics.

PHENALGIN.

PHENALGIN is an ammoniated, synthetic, coal-tar product, manufactured by the Etna Chemical Company of New York. Technically described as belonging to the amido-benzine series, it presents itself in the form of a fine white powder, with a characteristic ammoniacal odour. Being practically insoluble, it has but a faint taste, and is consequently not disagreeable to take. It differs from most of the analgesics in that it exerts a stimulating effect on the heart. In doses of ten grains and upwards a sedative effect is produced, in addition to its unquestionable analgesic action on the sensory apparatus of the nervous system. These various actions are precisely those which a consideration of the chemical constitution of Phenalgin would lead one to expect, and this is a striking confirmation of the truth of the thesis promulgated some years since by Dr. Lauder Brunton in respect of the inter-dependence of chemical constitution and physiological action. The stimulating effect of the ammonia constituent is first perceived, and this is soon followed by a soothing sensation due to the gradual subsidence of the painful manifestations. Phenalgin appears to be an ideal agent for the relief of insomnia associated with neuralgic or rheumatic distress. Similarly, in dysmenorrhoa, not dependent upon obvious organic lesions, Phenalgin procures prompt disappearance of the pelvic misery. Like most drugs belonging to this series it is possessed of anti-pyretic properties and, as already stated, it has hypnotic as well as anodyne properties which enable it, in certain cases, to take the place of opiates, the use of which is attended by such marked gastro-intestinal disturbance. Its value in the treatment of acute rheumatism has not as yet been established on as firm a clinical basis as in the case of neuralgic and so-called functional affections accompanied by pain, but there is no obvious reason why it should not prove of service in combination with other antirheumatic remedies

Phenalgin is sold in powder, and in 2½ grain tablets for convenience of administration. As it is insoluble, the drug is best given in the form of tablets, or, if it be desired to associate it with other remedies, in the form of cachets.

The sole agent for the sale of Phenalgin in England is Mr. E. J. Reid, 11, Dunedin House, Basinghall Street, London, who we understand, will send free samples to any medical practitioner, on application.

Medical Rews.

Milk in Relation to Tuberculosis.

The Aylesbury Dairy Company, which is one of the largest purveyors of milk in the country, has adopted a very wise attitude in the now popular crusade against tuberculosis, and its action should remove any anxiety in the public mind regarding the purity of the milk supplied from its farms. We have previously referred to the precautions originated by the directors in 1868, but these have been developed from time to time as science and

experience have suggested, and the farms and distributing branches are now under the inspection of no less than fifteen medical officers, six veterinary surgeons, and four public analysts. Each farm from which the company draws its upplies is visited frequently and regularly by the Medical Officer of Health for the District; the sanitation, health of the farm labourers and their families, &c., all being carefully investigated by him, and the water used periodically analysed, both chemically and bacteriologically, in the company's laboratory. In case of anything being found unsatisfactory, the milk is at once stopped, but the farmer is paid for it in full; this guarantees him against loss, and makes it his interest to give immediate information. Further, a sample from every churn of milk received is taken and tested before the milk is sent out to the consumer, further samples are taken from the carriers in the streets and on their return to the depôts. In addition to the foregoing very stringent measures, the directors have, in view of the question of tuberculosis now so prominently before the public, taken the further precau-tion of having the whole of the cows from which their supply is derived individually examined by the Principal of the Royal Veterinary College. These precautions go even beyond the action recommended by the Royal Commission on Tuberculosis, and it affords us much pleasure to chronicle these important precautions, pour encourager les autres.

niversity College Hospital.

SIR JOHN STIRLING MAXWELL, Bart., M.P., has consented to preside at a Festiva! Dinner in aid of the funds of University College Hospital, at the Whitehall Rooms, Hotel Metropole, on Thursday, June 15th, next.

Dublia Hospital Sunday.

The meeting of the Council of the Fund, preparatory for the annual public meeting, was held last Thursday, the meeting not being open to the Press. The total amount received (£4,285) was £71 worse than la-t year, and would have been worse still but for a donation of £100 by a baronet in the north of County Dublin. The distributable amount is £4,020.

A Vict m of Alcohol.

An inquest was held at Liverpool last week on the body of Mr. Albert Ryan, a medical practitioner in charge of a dispensary. The evidence showed that death was attributable to an epileptic seizure, the result of chronic alcoholism, and a verdict to that effect was returned.

Congress of Medical Life Examiners.

The first international congress of medical examiners for life assurance is announced to take place at Brussels on September 25th. In view of the interest of many of the problems to be discussed, the meeting is likely to be largely attended, and it cannot be gainsaid that there is ample material for very useful discussions

Diphtheria at Aldershot.

An inspector has been dispatched by the Local Government Board to Aldershot to inquire into the causes of the prevalence of diphtheria in that district. For some time past the comparatively large number of deaths from this disease in both the camp and the town has given rise to anxiety.

Poisoning by Atropine.

A STRANGE case of poisoning, placing the lives of a whole family in jeopardy, is reported from Watford. The symptoms were those of belladonna poisoning, and the servant has since been charged with maliciously mixing with the pudding the contents of a bottle of "eye water" belonging to her master. Thanks to prompt antidotal measures four of the six victims are out of danger, but two still remain in a precarious condition.

The Scientific Value of Alcohol.

A MEETING of the British Medical Temperance Association was held on the 17th inst. at the Conjoint Examination Hall, Victoria Embankment, London, when Capt. P.W. O'Gorman, D.P.H.,Indian Medical Service, read a paper on "The Scientific Valuation of Alcohol in Health." Dr. Morton presided in the absence of the president, Professor Sims Woodhead, through illness. The paper gave an excellent summary of facts and experiments with

respect to alcohol. The conclusions of the lecturer were that alcohol did not act as a food, that it did not retard waste but was a protoplasmic or tissue poison, that it did not impart energy, but was essentially a nerve paralyser, that it was dangerous both in hot and cold climates, and that it did not conduce to longevity. pointed out that it reduced vascular tension, and that Prof. Martin had shown that the strength of the heart contraction is diminished by alcohol. Dr. Ridge, in moving a vote of thanks to the lecturer, said he hoped the paper would be published, as he had found many medical men entirely ignorant of the immense number of facts which had accumulated proving the harm done by alcohol even in moderate doses, and the advantages of total abstinence; these things were not taught in the usual way, but there was some hope for the future, as there were between 300 and 400 medical students who were abstainers and belonged to the Association. The vote was seconded by Dr. Claude Taylor, and carried unanimously.

The Reid Trust for the Education of Women.

THE Trustees of this Fund have decided to offer a Scholarship at the London (Royal Free Hospital) School of Medicine for Women in memory of their valued cotrustee, Miss Bostock, of Penmaen, Glamorganshire, lately deceased. The value of the Scholarship will be £60 a year, tenable for two or four years, and awarded on the result of the Preliminary Scientific Examination of the University of London. The Bostock Scholar must read for the London Medical Degree. Further particulars may be obtained from the Hon. Secretary of the Reid Trust, Bedford College, York Place, London, W.

An Unqualified Apothecary.

Thomas Allen, of Commercial Road, E., an unqualified practitioner, whose name cropped up a year or two since in connection with a charge of covering against one Costelloe, has been fined £20 and costs for having acted as an apothecary without authority. The defendant had previously been cautioned by the coroner in respect of his conduct.

The Mortality of Foreign Cities.

The following are the latest official returns, and represent the last weekly death-rate per 1,000 of the several populations:—Bombay 89, Madras 44, Paris 20, Brussels 20, Amsterdam 14, Rotterdam 15, The Hague 14, Copenhagen 17, Stockholm 27, Christiania 34, St. Petersburg 28, Moscow 25, Berlin 17, Hamburg 14, Dresden 16, Breslau 21, Munich.—, Vienna 21, Prague 26, Buda Pesth 22, Trieste 33, Rome 18, Venice 24, New York (including Brooklyn),—, Philadelphia—.

PASS LISTS.

Army Medical Service.

THE following is an official list of successful candidates for Commissions in the Royal Army Medical Corps, at the recent examination in London, arranged in order of merit:—

	Marks.	Marks.
Delap, G. G	2,393 Murison, C. C	2,052

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

MR. ALBERT E. Morison (Hartlepool).—Your paper on "Four Cases of Intussusception," is marked for early insertion A note has been made of the other request.

THE Medical Directory for 1890 gives the number of tractitioners of all categories as close upon 35,000. This represents an increase of ninety-over over the figures of the previous year—an extremely small excess. London alons accounts for 6,17 medical men of this total, the rest of England absorbing between fifteen and six een thousand practitioners. In the naval, military, and Indian services there are 2,524 doctors.

PROFESSOR GAILLARD'S Clinical Lecture on "Pyo-pneumothorax from Necessity," received from our Paris correspondent with

D. H. G.-Great improvement has already been effected in the direction you advocate, only tweety-eight out of 7,428 inquests having been held in public-nouses.

THERMOMETRIC CALCULATIONS.

FROM Centigrade to Fahrenheit,
'Tis easy to divine—
You first must use arithmetic And multiply by nine.

The answer now divide by five, And then you have in view The very number that you seek By adding thirty-two.

From Fahrenheit to Centigrade, However, it is plain— You first must take the thirty-two And multiply again;

But this time only by the five
And then you draw a line
Straight up and down, in order that
You may divide by nine.
(The Corpuscle.)

Dr. WM. EWART'S paper on "The Relation of Gout to Rheumatoid Arthritis" received.

DR. J. R. WOLFE (Melbourne). - Paper on "Serum Inoculation"

Meetings of the Societies and Tectures.

WEDNESDAY, FEBRUARY 22ND.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Dr. T. G. Brodie: Erasmus Wilson Lecture on "The Chemical Pathology of Some Infective Diseases."

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.)—4.30 p.m. Informal Exhibition of Cases. 5 p.m. Ordinary Meeting.

HUNDERIAN SOCIETY.—8.30 p.m. Mr. C. J. Symonds: The Value of Individual Symptoms in Perforative Peritonitis, more especially in regard to operation.

THURSDAY, FEBRUARY 23BD.

ROYAL INSTITUTION OF GREAT BRITAIN.—3 p.m. Professor McFadyen on Toxins and Antitoxins.

TURNER, C. E., L.R.C.P. Joud., M.R.C.S., House Surgeon to the Royal Bucks Hospital, Aylesbury.

Births.

HALDANE.—On Feb. 13th at Viewforth. Bridge of Allan, N.B, the wife of William Haldane, M.D., F.R.C.P., of a son.

Marriages.

WOODS—CHALONER-SMITH.—On Feb. 11th, at St. Bartholomew's Church, Dublin, Hugh Woods, M.D., of Highgate, to Tempe, elder surviving daughter of the late John Chaloner-Smith, C.E., of St. Helen's, Bray, co. Wicklow.

Beaths.

Monckton.—On Feb. 18th, at Wimbledon, Mina, widow of the late Stephen Monckton, M.D., F.R.C.P., of Maidstone. RANSFORD.—On Feb. 18th, Gifford Ransford, M.D.Durh., of Sussex Square, London, W., aged 5t. BOR.—On Feb. 18th, in London, Edward Roe, M.A.Cantab., L.R.C.P., M.R.C.S.Eng., of Lyndhurst, Hants, aged 53.

"Allenburys" Foods koo

Infant Feeding

progressive series of foods.

~10ToE~

The Foods constituting the series described below are not interchangeable, but should be used in succession as indicated. Perfectly sterile in themseives, they are best given with the "Allenburys" Feeder, which is capable of easy and complete sterilization, thus presenting a physiologically accurate diet, free from all fear of contamination by the products of decomposition.

"Allenburys" Milk Food No. 1

Affords, when prepared for use, a correct substitute for human milk. It is manufactured from fresh cow's milk, so modified as to present all the constituents of human milk in their true relative proportions. Being in a desiccated and sterilized form, it requires only the addition of boiled water to obtain a pure and sterile food suitable for infants during the first three months of life.

"Allenburys" Milk Food No. 2

Is identical with No. 1, with the addition of small quantities of maltose, dextrine, and soluble phosphates derived from the digestion of whole meal with Malt Extract. These ingredients are a valuable adjunct to the increasing needs of digestion, yet the Food is readily and easily assimilated, there being no unconverted starch present. The No. 2 Food is designed for children between three and six months of age.

"Allenburys" Malted Food, No. 3.

USUALLY KNOWN AS

Allen & Hanburys' Malted Infants' Food,

Is not a milk, but a purely farinaceous Food, prepared by improved methods after Baron von LIEBIG'S formula. The basis is fine wheaten flour, which has been thoroughly cooked and partially digested by an active Malt Extract, so that a large proportion, but not all of the starch has been converted. It is particularly rich in soluble phosphates and albumenoids.

This Food should be given from six months and upwards. For the first month or so after the change of diet it is generally advisable, instead of using cow's milk, to employ the "ALLENBURYS" MILK FOOD NO. 1 or No. 2 in preparing it. The demand on the child's digestive organs is less abrupt, and a humanized milk is used in place of the more indigestible cow's milk. This precaution is specially recommended in the case of delicate children.

The "Allenburys" Feeder.

This bottle has the nipple at one end and a valve-stopper at the other, so that, both being removed, it can readily be cleansed under the tap. The valve admits air behind the column of milk, thus avoiding the swallowing of air and the resulting wind-colic; while the rubber nipple is easily detached, and can be turned inside out. The bottle is graduated approximately in ounces

The "Allenburys" Thermometer, in nickel case, as figured, is provided for determining the right temperature at which the Foods should be given, and for general Nursery use.

Plough Court, Allen & Hanburys l Ta., Lombard Street, London.

Infants' Food Manufactory: WARE MILLS, HERTFORDSHIRE.

For further details concerning these Foods, see succeeding numbers of the British Medical Journal and Lancet D

The Ideal Tonic?

VIBRONA contains all the tonic and aromatic principles of Cinchona and is therefore superior to Quinine alone.

VIBRONA is pleasant to take, and does not produce the headache, deafness, or other disagreeable sensations caused by Quinine.

VIBRONA is entirely free from Coca, "the third scourge of humanity." (vide British Medical Journal.)

Because VIBRONA has proved invaluable in the treatment of Anæmia, Neuralgia, Insomnia and Nervous Exhaustion.

VIBRONA is found to accelerate in a remarkable degree recovery from Diphtheria, Influenza, Pneumonia, Typhoid, and other wasting diseases.

Because VIBRONA, not being a secret remedy, has gained the confidence of the highest medical authorities.

VIBRONA per bottle 4/-., per dozen 45/VIBRONA-SHERRY ... per bottle 2/9, per dozen 30/VIBRONA-CHAMPAGNE ... per doz. pints, 38/-, per case 72/VIBRONA-MALT ... per bottle 2/6, double size 4/6.

Supplied by all leading CHEMISTS, WINE MERCHANTS AND STORES

Or carriage paid from FLETCHER, FLETCHER & Co., HOLLOWAY, LONDON, N.

Original Communications.

ON THE RELATION OF GOUT

RHEUMATOID ARTHRITIS.

OPENING REMARKS TO A DISCUSSION BEFORE THE NORTH-WEST LONDON CLINICAL SOCIETY, FEBRUARY 15TH, 1899.

By WM. EWART, M.D., F.R.C.P,

Senior Physician to St. George's Hospital and to the Belgrave Hospital for Children; Joint Lecturer on Medicine in the Medical School of St. George's Hospital.

In opening a discussion in which so many are invited and ready to take part my most important duty is to be brief; and a further duty is to submit for your consideration some of those points which seem to be most in need of elucidation.

The leading note in my few remarks will be that the relation between gout and rheumatoid arthritis is rather accidental than essential, and that when the two affections happen to combine, this conjunction is but one of many varieties included under the broad heading to rheumatoid arthritis.

The relationship between gout and rheumatoid arthritis may be profitably considered from two points of view—the purely theoretical or pathological aspect, including their ætiology and their morbid anatomy, and the practical or clinical aspect, which is concerned with the natural history of the diseases, with their diagnosis and with the results of their treatment; and it is only from a joint study of all those aspects that we can hope to derive any true insight into the relation which may exist between them.

Within this hour it would be impossible to deal systematically with so large a subject, but out of it arise a few definite questions, to which I may at once call your attention. I venture to submit to you the following:—

 Are gout and rheumatoid arthritis directly antagonistic, so as to exclude each other; or are they capable of affecting the same subject?

2. If not mutually exclusive, are they capable of actually ecexisting, or can they only occur at an interval of time in the same individual?

3. If the relation is one of sequence rather than of coexistence, does rheumatoid arthritis pass into gout, or is it gout which may lapse into rheumatoid arthritis?

is it gout which may lapse into rheumatoid arthritis?

4. The remaining questions are those of diagnosis and of treatment, a discussion of which cannot fail to be of practical use.

The Pathological Uncertainty as to Rheumatoid Arthritis.

At the outset I encounter a difficulty which others may also realise. Whilst gout, in spite of the obscurity of its ætiology, is probably, for all of us, a sufficiently definite clinical unit, and whilst we are all probably agreed as to its material basis, I am not confident that under the name of rheumatoid arthritis we all recognize a thoroughly well defined and uniform disease. Yet some general agreement as to the meaning of the term is essential to the success of the discussion.

Most of us have probably been struck with the variety of conditions included under that name, and with the number of theories which have been put forward, and this must incline us to suspect that we may have to deal not so much with different phases and with different presentments of a single disease, as with different affec-

tions among which at least two and probably three or more separate diseases will ultimately be isolated.

Looking specially at the clinical aspects, I have long been impressed with an apparent distinction between two ets of cases, the group of "gouty" rheumatoid arthritis ind that of "rheumatic" rheumatoid arthritis; but I am willing to admit that this is too superficial and perhaps too exclusively clinical a division which, moreover, teals only with a limited section. There is a larger section comprising various types which are neither gouty nor rheumatic.

The futility of former endeavours to explain all cases by any one theory has led to an attempt to split up the group, and to contract the boundaries of rheumatoid arthritis by excluding the chronic senile monarthritic variety. And recently part of the group has been reconstructed on a bacteriological basis. You are probably all acquainted with the bacteriological work of Bannatyne, Wohlmann, and Blaxall. Max Schüller, (a) to whom we owe the earliest bacteriological observations, now goes so far as to separate as the strictly infectious form of rheumatoid arthritis, the villous affection of the synovial membrane, Arthritis chronica villosa, which he has been able to produce experimentally in animals, and which he has treated successfully in man, both surgically and by intra articular medication.

I need not point out that the infectious group can

I need not point out that the infectious group can present but little affinity with gout, and that further evidence must be forthcoming before we can admit that a bacterial erigin has been proved in all the varieties. This would still leave upon our hands the monarthritic varieties which are not senile, and two or three different types of the polyarthritic affection, besides the affections following upon traumatism, and upon septic, gonorrhœal, tuberculous, and syphilitic lesions. And we may, therefore, still ask, What is Rheumaotid Arthritis?

The Characteristics of Rheumatoid Arthritis.

The definition of rheumatoid arthritis would have to be reduced to a very simple expression to fit all cases—that of the pale child with symmetrically swollen and shapeless joints, and, perhaps, as in the cases recently described by Dr. G. F. Still, with swollen glands; of the young adult with stiffened articulations and unbending spine, of the woman of mature years with Heberden's nodules and easily excited articular pains, and of the veteran whose longevity declares his original soundness, but who has long been crippled with a wasted and eburnated his joint.

In this long gallery of deformities, of which I have only mentioned a few, the chief common features are constitutional and local. Constitutionally the affection is chronic and progressive when left to itself; it is a disease of depressed nutrition and of debility. Locally it is also chronic and progressive if allowed to advance. Its lesions are not metastatic but permanently localised. They are essentially degenerative, with marked tendency to overgrowth In varying degrees according to cases, it affects each of the constituents of the joint, but more markedly perhaps the cartilage. But the cause of the degeneracy is not obvious, though its results are considerable. In this it differs from gout. And from the common form of rheumatism it differs in all cases by the extent of the destruction and by the permanence of the lesions; in the monarthritic varieties by the strict limitation, and in the polyarthritic varieties, by the symmetry as well as by the number of the joints affected, and there is also a greater tendency to an implication

⁽a) Cf. Verhhandl. des xv. Congress für Inn. Medicin.

of the small joints as well as of the larger ones; whilst in acute cases the acuteness is less than in rheumatism, and there is less profuseness and acridity of perspiration. The constitutional influence of the disease is not marked by visceral degeneracies as that of the kidney in gout, nor so frequently by complications such as those of the serous membranes and of the heart, as in rheumatism.

Thus, with the exception of the marked peculiarity of the degeneration, those pathological features which are common to all cases are to a great extent negative, and consist of nothing more definite than the permanent localisation and the dystrophic character of the lesions. They point in other words to perverted local nutrition combined with constitutional debility and mal-nutrition as to the essentially rheumatoid characteristics.

The Theories.

Owing to this comprehensive broadness of type, considerable scope is given to our speculations as to the latent cause, and theories have been freely supplied. To call the affection gout is, pathologically speaking, out of date, though not always out of fashion. To regard it as rheumatism is a large postulate in face of many pathological and clinical discrepancies; and we cannot forget that the ætiology of rheumatism itself is a mystery. Some regard rheumatoid arthritis as a form of senile decay, and others as the outcome of some traumatic lesion which has failed to recover, an explanation which is plausible only in the monarthritic cases. But these views hardly explain the early adult and especially the juvenile cases, and those cases in which no lesion can be found. Lastly, we have the more ambitious theories which seek an adequate explanation in some disordered state of the great agents of nutrition, the blood on the one hand, and the nerves on the other; these are the neural and the humoral or toxic theories.

It is obvious that these theories cannot all be right—yet they represent the conclusions of thoughtful observers, and. perhaps, none of them may be absolutely wrong, but they may be partially, if not absolutely applicable in different cases. The fact of the discrepancies between them is a strong argument as to the want of unity in the group of rheumatoid arthritis, and also as to a possible co-operation of many factors in individual cases.

Rheumatoid Arthritis viewed as a Morbid Result rather than as a Disease.—The variety almost amounting to opposition in the theories as to the nature of rheumatoid arthritis suggests strongly that an attempt may have been made to describe as a disease that which may be essentially a result. If the familiar changes might be regarded as the progressive stages, varying freely in their individual developments, but agreeing in their terminal condition, of the non-suppurative variety of degeneration of joints it would be conceivable that various diseases, gout, rheumatism, tabes, gonorrheal infection, as well as simple injury, might lay the foundation of the mal-nutrition in question.

There might still be room for the recognition of hitherto imperfectly proved agencies, for instance, for the subtle influences of bacillary infection, or of peripheral nerve affections whether of a structural or of a functional kind, as direct causes for those varieties which are not manifestly connected with any constitutional disease or local factor, and are therefore classed as "spontaneous" or "pure" cases of rheumatoid arthritis. We might then more easily reconcile divergent theories, because no longer claiming a pathological unity for the clinical types. It might be possible to regard the trouble sometimes as essentially a tissue degeneration, and to this view correspond the suggestions of traumatism, senility, and disease as possible causes, and sometimes as a definite disease.

In dealing with rheumatoid arthritis as a disease we should have to leave aside as incapable of any general application the theories of traumatism, of senile decay, and of pure gout, and to choose between three hypotheses:

(1) the neural theory, (2) the infective theory, and (3) the rheumatic theory with its two chief modifications—the one being (a) that rheumatoid arthritis is a hybrid between g ut and rheumatism, the other (b) that it is a systemic disease distinct from gout and from rheumatism.

vet possessing analogies with both, Or, if it had to be viewed as a specific disease entirely distinct from gout and from rheumatism, then only two adequate theories as to its production would remain—the neural and the toxic. In favour of both, weighty arguments have been brought forward. On the on, hand, a strong point has been made by Dr. Ord of the frequent coincidence of the affection with uterine and ovarian troubles, and with catamenial irregularity, amenorrhœa, and the menopause. This, he believes, indicates a reflex nervous mechanism of production. Arguments are also derived from the considerable wasting of the muscles, from the occurrence of peripheral neuritis, from the alterations in the myotatic reflexes, and from the close analogy of the articular lesions of tabes with the rheumatoid lesions. On the other hand, a bacillus has been described by Schuller, Bannatyne, and others, by which a destructive toxin might be elaborated.

Considerable importance also attaches to the view put forward prominently by Mr. Macnamara (a) and according to him originally suggested by Todd, who ascribed certain joint affections to putrid discharges from the vagina, that the intoxication may be of a non-specific nature, viz., such as may arise from disordered metabolism or impeded excretion, or be due to poisons manufactured within the organism (such as ptomaines produced by suppuration), rather than to germs imported from without. Arthritis may be caused by "the passage into the blood of the chemical products of inflammation rather than to the direct entrance of the microbes into the affected joints." Mr. Macnamara has made the further suggestion that decayed teeth may be in many cases the source of an infection to which the joints may react in a manner analogous to that which we observe in arthritis due to gonorrhea, pyæmia, scarlet fever, and various other infections. These suggestions possess much weight and deserve our close attention.

It is noteworthy that one of the affections so well described by Dr. Still (cf. Clifford Allbutt's System of Medicine, vol. III.) as apt to occur in a somewhat acute form in children, is stated by him not to develop usually before the period of the second dentition. This would coincide with the time of decay and absorption of the temporary teeth.

The Clinical Basis of the Theories.—The neural theory and the humoral or toxic theory have both appealed to

the same clinical facts.

Thus the high tension and increased pulse rate, insisted upon by Kent Spender, and the liability to palpitation noted by Duckworth might equally be regarded as vasomotor agencies, or as Jue to the action of irritating principles in the blood.

Catamenial irregularities, amenorrhoa, and the menopause, ovarian and uterine affections, mental shock, have

all their neural and their humoral aspect.

The pigmentary changes pointed out by Kent Spender and the increased myotatic irritability, are not constant phenomena, but they belong decidedly to the province of the nervous system.

General Etiology .- In dealing with the general etiology, predisposition cannot be entirely disregarded. Rheumatoid arthritis does not present that directness of transmission which is a feature of gout. Indeed, we look in vain for that something which could be transmitted. unless it be a general liability to articular disease. An element of truth is probably contained in the popular view which credits certain individuals with a definite structural weakness of some one or other of their organs, be it weak lungs or weak kidneys, or a weak heart. Morbid functional peculiarities may run along given lines of structural weakness, and whether we shift this supposed imperfection from the joints to a cerebrospinal joint-centre, or localise it in the articulations themselves, there is some reason for admitting that a delicacy of the joints may be inherited. Gout and its associate diabetes, rheumatism, and phthisis are among the most prevalent of our diseases, and we must be prepared to find them largely represented in the family histories of the rheumatoids; but there is significance in the fact made out by Sir A. Garrod

⁽a) Proceedings of the Royal Medico-Chirurgical Society. Third Series. Vol. XI, p. 48, 1899.

that of these three influences that of gout is the progenitor is by far the most frequent.

Vulnerability.-Without attempting to discuss the well-known but unexplained susceptibility of joints to the action of various morbific agencies, as, for instance, of gonorrhoa and other infective poisons, we are almost led to assume a relatively increased vulnerability of the joints in the subjects of rheumatoid arthritis as an explanation for their unhappy reaction to influences of climate, soil, atmosphere, and occupation which leave stronger subjects unaffected. Other causes sometimes alleged, traumatism, disturbed internal mechanism of the joint or dislocation, paralysis or prolonged disuse will not of themselves produce the disease. Undue vulnerability must be called to aid before we can account for these alleged causations.

The vulnerability referred to is closely connected with the question under discussion, inasmuch as it might explain the late development of rheumatoid changes in joints as a result of previous gouty lesions, without the intervention of any fresh and additional disease.

THE RELATION BETWEEN GOUT AND RHEU-MATOID ARTHRITIS VIEWED FROM A BROAD STANDPOINT.

Enough has been said to justify a suspicion that the rheumatoid conditions do not form a homogeneous unit but they may result from various influences and assume different types of development. Since they have always been described under one heading the assumption is that they are kept together by a central well-defined type which has served as the backbone of the entire group, and that it is to that type that the term rheumatoid arthritis properly belongs. This is the type more speci-

ally considered in my present remarks.

Gout and Rheumatoid Arthritis contrasted.—Had we been asked to discuss the relationship between rheumatoid arthritis and rheumatism, there would have been no difficulty in tracing many points of contact between them, and no lack of variety in the opinions which would have been elicited, for the question which this relationship involves remains to the present day one of the funda-mental and most debatable questions in the pathology of

arthritis deformans.

Between it and gout there is much less obvious affinity and at first sight little to debate upon. Yet we are invited to take the matter under consideration; and since we must discuss it, we shall probably discover sufficient material. If I were asked to broadly define the relationship between gout and rheumatoid arthritis I would state it to be one of contrast, not of resemblance. There is no relation between them. They differ from each other all along the line of clinical symptoms and of pathological changes, with the exception that they are both in their later developments deforming and crippling affections, and that some minor characteristics are common to both

Constitutionally they are most unlike. Rheumatoid arthritis, as its name implies, is nothing if it is not a local joint affection. It is apt to shorten life, but this is chiefly due to the deleterious results upon the general health of the antecedent crippling. Gout is not confined to the joints. Its most fatal results are largely independent of the local articular trouble and are exerted directly upon the kidney, the heart, and the blood vessels, and sometimes also upon the visceral functions, indepen-

dently of any coarse structural changes.

It would be rash to assert that there is not a constitutional ens morbi in rheumatoid arthritis; some peculiarities rather suggest that there is. But we are agreed that this ens morbi, if it exists, is much less prominent. And although future investigations may perhaps reveal its power of damaging the vital organs and functions, this power has hitherto been much less obvious, nay, even latent, and the field of its workings totally different from that occupied by gout. For instance granular kidney and albuminuria, and atheroma of the blood-vessels, which are the chief dangers of gout, do not form an essential part of the natural history of rheumatoid arthritis.

Moreover, we notice at first sight that the constitu-tional types attacked by the two diseases are in obvious contrast. The gouty, in general, are apt to be full-

blooded; those who develop rheumatoid arthritis weakly and anæmic.

Clinically the line of distinction is no less sharply drawn. Rheumatoid arthritis selects some of its victims at a relatively early age; with gout, pre-eminently a disease of middle age, this is exceptional. The female sex, which suffers much less often and much less severely from gout, contributes a large majority of the cases of rheumatoid arthritis.

The march of the two diseases is also singularly different The onset of gout is commonly much more abrupt and acute, and confined to a single joint. That of rheumatoid arthritis, in perhaps its most common form, is relatively gradual and often insidious, and in the typical cases many joints suffer and symmetrical joints

are affected.

Pathologically, what do we find? In gout sodium biurate is traceable in the joints and in their coverings, as well as in the tophi. Nothing of that kind is to be discovered in the straightforward cases of rheumatoid arthritis, and an excess of uric acid in the blood has also been looked for in vain. Locally the pitting and superficial ulceration of cartilages may be a relatively early event in gout. In rheumatoid arthritis the early event is swelling and overgrowth of cartilage, destined in typical cases to be a permanent feature, but accompanied later by an extensive destruction of the hypertrophied cartilage and by a varying amount of ossification.

In the later stages some of the local results are analogous. Lipping of the cartilage is seen in some of the chronic cases of gout, and it is the rule in arthritis. Distortions occur in both which, though essentially different, may sometimes present a rough resemblance. In gout they are due most often to the peri-articular thickenings

which are apt to supervene.

Looking at the therapeutical side of the question, we discover no less marked a contrast. To climate, atmosphere, and soil the reaction is almost identical, but in every other respect there is an opposition in the effects produced by medicines and other measures of treatment, and by diet.

(To be concluded in our next.)

COMPLETE REMOVAL OF FETUS AND SAC IN A CASE OF ADVANCED EXTRA-UTERINE PREGNANCY.

By MAYO ROBSON, F.R.C.S.,

Professor of Surgery in the Victoria University; Senior Surgeon, General Infirmary of Leeds; Honorary President International Gynæcological Congress.

IT is not my intention to invite a discussion on the pathology and classification of extra-uterine gestation, as the subject has been recently considered by a Fellow of the Society, Mr. Taylor, in his very instructive Ingleby Lectures for 1898, and by myself in my Valedictory Presidential Address before this Society; nor do I propose to consider the treatment of the early stages of the disease, but to limit my remarks, first, to the report of a case in which I removed the entire fœtal sac, together with the fœtus, two months after the full term of pregnancy, and, secondly, to the treatment of advanced extra-uterine gestation generally.

Mrs. R-, et. 29, was seen by me with her own medical attendant, Dr. W-, on September 29th, 1898, when she gave the following history: -She had had two children, the last five years ago. Since the birth of the last child she had been quite well, and had menstruated regularly until September 20th, 1897, when she was unwell for three days, the loss being somewhat excessive. The next period was due on October 18th, but nothing showed until three days later, after which metrorrhagia continued to January 15th. On November 29th she received a terrible mental shock from suddenly finding her father dead. Almost immediately the metrorrhagia changed into profuse bleeding, and several clots were passed. As the bleeding continued Dr. W— was asked to see her for the first time on December 6th, and it was then thought that she had had a miscarriage. tumour could be detected on palpation of the abdomen, and the sound passed 2½ inches. On December 13th there was still no evidence of tumour, though the bleeding was continuing. Christmas a tumour could be detected bi-manually. and this had increased so rapidly that, when on January 15th she was seen by a specialist in consultation with Dr. W——, the tumour was palpable above the pubes on the left of the middle line. The sound then passed to the right of the tumour, and Dr. — thought it a case of myoma; but when he saw the patient again on February 7th, the tumour reached to the umbilicus, and the sound still passed to the right; the diagnosis being then altered to one of pregnancy in the left horn of a bicornuate uterus.

as the fœtal heart sounds could be distinctly heard.

After January, there was no uterine discharge until June, when there was a slight "show," which soon ceased. In July, just a month later, a coloured uterine discharge again appeared, and from that time up to being seen by me in September there had been more or less metrorrhagia, and during the past four weeks this had been excessive and bright in colour. In January, the tumour steadily increased in size, and at the end of July she was again seen by Dr. specialist, who then thought her seven months advanced in pregnancy, but on the same evening the fætal movements, which had at first been observed in February, became more excessive and energetic, and labour-like pains came on so severely that morphia

had to be given hypodermically.

From that time all feetal movements ceased. There were then milk in the breasts, and all the other signs of pregnancy. When seen by me on September 29th I found the abdomen occupied by a large tumour (as shown in the diagram), and a bi-manual examination revealed the uterus pushed to the right, the fundus being easily made out separate and distinct from the tumour itself, and the uterine sound could be passed for a little over the normal distance. The roof of the vagina on the left was somewhat pushed down by the tumour so that the cervix was placed more to the right than to the left. Ballottement could not be obtained either from side to side or per Auscultation failed to reveal either the sound of the feetal heart or the placental bruit. diagnosis of extra-uterine gestation was made, and early operation was advised, since the fœtus was mani-festly dead, and the patient's health was becoming seriously deteriorated as the pulse was persistently rapid, from 110 to 120, and there were considerable loss of flesh, a hectic flush on the cheeks, and a temperature each evening.

On October 4th, Dr. W- giving the anæsthetic, and Dr. Macrae assisting at the operation, I opened the abdomen in the middle line and found the feetal sac on the left of the uterus, from which it was separate and distinct. The sigmoid flexure of the colon was crossing its upper part, and the omentum was adherent to the front of the sac. After packing sponges around, I opened the thin part of the sac in front and removed a quantity of dark, inodorous, grumous fluid, afterwards extracting the child. After a careful examination I found it would be possible to completely remove the sac. I therefore ligatured off the ovarian vessels externally, and made a pedicle between the uterus and the sac internally. I then detached the omentum ligaturing several adherent portions, and dividing between ligatures. I then separated the anterior layer of the meso-sigmoid which was expanded over the sac and found that I

could easily shell the tumour from its bed, the only difficulty occurring in one or two places where the posterior layer of the meso-sigmoid carried the large intestinal vessels and was rather adherent to the sac. After the separation of these adhesions I had a few vessels to ligature. The detached part of the sac vessels to ligature. enucleated without difficulty. Although the peritoneum appeared to be perfectly dry I thought it wise to nsert a glass drainage tube for 24 hours. The next morning there was so little discharge that it was felt safe to remove the drainage tube.

The wound healed by first intention and the sutures were removed on the seventh day. After the first day the temperature and pulse were perfectly normal, and recovery was uninterrupted. The patient is now

in good health. Specimen shown.

A quotation, Sir, from your own text-book (Macnaughton Jones' "Diseases of Women," p. 595), would seem to show that removal of the entire sac is not worth considering after the fourth month.

"When the gestation has not advanced beyond the fourth month, it is sometimes possible to remove embryo, tube, ovary, and sac by transfixing the broad ligament as in a simple ovariotomy. When the ligament as in a simple ovariotomy. pregnancy has advanced beyond the fourth month. the placenta has become too large to be thus dealt with. The sac is then exposed, through an abdominal incision, the fœtus, placenta, and clot evacuated, the bleeding checked with sponges, the edges of the sac are then stitched to the abdominal incision and its cavity drained. After the fifth month operation must be considered under two headings:

"1. The Treatment of the Sac.

"2. The Treatment of the Placenta."

Mr. Taylor, in his Ingleby Lectures, recommends removal of the placenta in tubo-abdominal pregnancy, and drainage of the sac in tubo-ligamentary pregnancy, but does not advocate removal of the sac, which he describes as unnecessary and dangerous.

In Dr. Kelly's work, "Operative Gynæcology." vol. 2, p. 457, complete removal of the sac is advocated wherever it is practicable on account of the danger to life from the possible infection of the large placental mass, and from the danger of secondary hemorrhage due to the breaking down of recent thrombi when the placenta is separating piecemeal at a later date.

From the description I have given of the removal of the specimen on the table it will be recognised that the operation presented no extraordinary diffi-culty beyond what would have occurred in removing a large multilocular or dermoid ovarian cyst that had invaded the meso-sigmoid; in fact, I have performed many ovariotomies that have presented much greater difficulties and which have recovered without unusual complications as in the case under discus-

I would offer for discussion the following points in the treatment of advanced extra-uterine pregnancy.

On opening the abdomen, if the fœtus be found among the intestines, the cord should be divided and the fœtus removed; if the placenta be attached to the expanded tube it can probably be removed, as suggested by Mr. Taylor, but if spread over the intestines or large pelvic vessels its removal will be unsafe. and gauze packing of the placental area and drainage will be the safer method, the placenta having been cleared of blood and cleansed as much as possible.

If the feetus is enclosed in a sac this should be opened at its thinnest part and the foctus extracted; the sac should then be carefully examined to ascertain if its removal is feasible. If thought practicable, the preliminary ligature or clamping of the uterine and ovarian arteries will simplify the subsequent procedure. All intestinal and omental adhesions must be dealt with by peeling them off where feasible and ligaturing where necessary. The deeper parts of the sac will be easily dealt with, if, as is usual, the attachment of the placenta is at the upper part. It will do no harm if very adherent portions of the sac be left, should their detachment present unusual difficulties. Subsequent drainage for twenty-four hours with a glass tube is, to my mind, both safe and useful in these and similar cases, and with proper antiseptic precautions is not, in my experience, attended with risk of infection.

SYPHILIS IN THE ARMY, 1812-1896. BEING A REPLY TO

MITIGATION AGGRAVATION OF AND SYPHILIS.

By JOHN A. SHAW-MACKENZIE, M.D.Lond.

(Concluded from page 186.)

(d) "Mitigation," "Self-exhaustion," "Self-extinction.

These terms are by no means synonymous, as possibly might, at first sight, be inferred. Very numerous are the adduced causes of mitigation or modification in syphilis, and Fergusson himself when he adduced the attenuation theory directed attention to the mitigating effect of climate, which has received the support of numerous observers in various

places other than Portugal.

For instance, Acton, in 1860 refers to Wilde's observations on mitigation of syphilis in Austria assisted by temperance, hygiene, and non-mercurial treatment. The hard sore was practically unknown, but various intensities of syphilis were noted in different countries, Lisbon being mentioned. Acton, in referring to the later work of Fergusson, and supporting the aggravating effect of climate, campaigning, and abuse of mercury, enjoys with Dr. Ogilvie the melancholy distinction, in my opinion, of regarding Fergusson's admissions in respect of the abuse of mercury in the light of "confessions."

Dr. Ogilvie explains attentuation by self-exhaustion in reference to the analogy of the natural smallpox by "acquired immunity hereditarily transmitted." Fergusson's original conclusion was "that the virulence of the disease has become so much mitigated by reason of general and inadequately resisted diffusion or other causes that, after running a certain (commonly a mild) course according to the known laws of its progress, it exhausts itself and ceases spontaneously."

Obviously Fergusson applies the term "self-exhaustion" to cases among the bulk of the Portuguese which got well without mercurial or very little mer-cury, irrespective of cause. "Diffusion" in syphilis is not restricted to "acquired immunity hereditarily transmitted," either generally or by Fergusson. He mentions hereditary syphilis it is true, but was unable to follow the cases up on account of the jealousies of the native faculty. He thinks such may continue from infancy to puberty, but was not yet disposed to believe that it could appear at puberty for the first time. Struma was, he thought, explainable by other causes than the venereal, but he in no way mentions immunity conferred by hereditary transmission.

indeed, among "other causes," he mitigation was occasioned by diffusion unresisted by mercurial treatment. The term "self-extinction can only be employed in the same sense as "self-exhaustion," that is, to the spontaneous cure of a mild disease in the individual. Fergusson does, however, state that "by the resistance we have opposed to syphilis and variola (by mercury, vaccination, and inoculation), we have retarded their natural decay among us. That we have made both more rare I

believe, and that we may finally succeed in extinguishing both I devoutly hope, but whenever we are revisited by either the one or the other, I fear they will not come to us disarmed of their terrors. Portuguese, through apathy, and at a dreadful price levied on the generations that are passed and never in all probability to be redeemed by their descendants, appear to have gained a great exemption from their immediate effects." It is only these latter paragraphs which can justify any idea of complete immunity in the individual or extinction in the nation. The latter is opposed to his portrayal of revisitation, as also to his view of the *de novo* origin of syphilis, which his "friend Guthrie" also believed to be the case, "whenever prostitution is foul and unclean, restricted to few women amidst crowds of men, which afterwards spreads through society at large.

(e) Much importance is attached by Dr. Ogilvie to Fergusson's later paper which I have readily admitted in the first instant I was not aware of. "Written in the year 1843," says Dr Ogilvie, "it bears witness to a total change of his (Fergusson's) views regarding it (mitigation by self-exhaustion), and which seems to have escaped the notice of nearly all those who have written on the subject. My attention has been drawn to it by the first edition of Drysdale's work (12). The only other author who refers to it as far as I have been able to ascertain, is the learned historiographer

of venereal disease, T. K. Proksch.'

In this paper Fergusson fully testifies to the aggravation of syphilis among the British troops in Portugal by the abuse of mercury, and makes no mention of attenuation.

This paper, Fergusson tells us, was "but a frag-ment intended to fill up a gap in the systematic treatment and history of syphilitic diseases. Let it be taken for what it is worth, a military sketch of a period when a discovery of much importance in regard to the treatment was made, and a mighty error was exposed and corrected.

In his introductory remarks he states: "I have now arrived at that period of life when its game has been nearly played out. . . I shall therefore, using another privilege of my age, venture upon the task without fear or favour to any authority, or school or party, but taking what I believe to be the spirit of truth for my guide, fearlessly tell it in every part of my subject, always, however, eschewing personal offence and needless injury to the feelings of the living or memory of the dead. For nearly fifty years I have been an indefatigable scribbler. but the health of armies was, above all, the shrine at I have not unfrequently which I worshipped. . . which I worshipped. . . . I have not unfrequently found parts and parcels in the pages of my contemporaries without at all recognising them as my own. . . . For candid criticism I shall ever feel most grateful, but I shall not reply to it otherwise than by correcting the errors and mistakes I may have fallen into in a second edition should this work ever be permitted to arrive at that distinction. I feel that I am past the age of controversy. Its triumphs would bring me little satisfaction, because I know they would stain my pages if achieved even temporarily at the expense of truth. I write not for the drawing-room, or the schools, or the circulating libraries, or for any time-serving purpose, but I write more especially and in the first instance to illustrate if I better can the British military character.'

Fergusson never lived to complete his work Shortly after the completion of the chapter on syphilis he was attacked by his last illness (hemiplegia), and from that time till his death in 1846, his editor-son-tells us "it remained sealed up in my hands. I am perfectly aware of many defects the work unfortunately possesses and . . . in the first place it is manifestly imperfect, ending abruptly with the article on syphilis without any peroration

or resumé, and I know it was my father's intention to have added considerably to it, besides correcting many minor defects in its passage through the press. But even had this been completed, it then would have been only half the intended work which was to have had a second volume comprehending his opinions and experience of the civil branch of his profession." Would further opinions have shed any light on the question of mitigation? I think not. He had substituted "idiosyncrasy" for attenuation in explanation of "the incontrovertible fact that the British Army at this moment contains thousands in perfect health, and has contained many thousands more who have been perfectly cured of every stage and state of syphilitic diseases without ever having taken a particle of mercury, although amidst the infinite variety of idiosyncrasies which the human race presents there can be no doubt that particular cases have occurred, and always will occur, in which the use of that remedy has been and will be found absolutely necessary." It is the explanation of "idio-syncrasy" which is now the point at issue. With "the greatest admiration and respect" for Fergusson it seems to me in this paper he was overwhelmed with the "mighty error" of the abuse of mercury (which he had done so much to expose) at the expense of explanation of those facts, Dr. Ogilvie omits to credit him with. And he was unmindful of Colles' (and Wallace's views) that "this disease appears to become less virulent as it becomes further removed from the fountain head." (13)

Six years later, even had he lived, Fergusson again might have had reason to revert to his original opinion. "We can scarcely understand how an impartial inquirer not led away by the necessity of upholding a theory, or not puffed up by an inordinate estimate of the transcendental value of everything modern, and a thorough contempt of everything old, can doubt that syphilis has undergone many and important changes in its external manifestations— now presenting itself in the most inveterate and intractable forms—then again within a single generation, and under the observations of men with as much brains in their head and as good eyes in their orbits as any modern syphilographer (to use the cant phrase) appearing in a milder and more manageable shape, so much as to induce more than once an almost universal hope in physicians throughout Europe that the malady might possibly wear itself out. When a malady then can alter its aspect, we cannot venture to dogmatically deny that it may manifest itself in forms which we never expected it could assume"

In 1854, not in 1863, nor "resuscitated from oblivion," as Dr. Ogilvie states, the late Mr. Henry Lee first fully testified to Fergusson's theory of attenuation (15). He at the same time pointed out that "the modification of the action of the syphilitic poison in consequence of repeated inoculation, although it has of late years assumed a new name, is not, as we have seen, a new subject," and that Fergusson pointed out, "the disease had become so much mitigated in Portugal by reason of general diffusion that after running a mild course it exhausted itself, and ceased spontaneously" in the bulk of cases. "It must be remembered," says Mr. Lee, in referring to the non-mercurial successful method of treatment adopted by Mr. "Rose and many other Army surgeons, that the cases which they have to do with occur in those who are often in some measure syphilised . . . their systems have in some measure become accus tomed to the influence of the poison, and the forms both of primary and secondary disease in them are most materially modified thereby . . . It is wellknown that individuals exposing themselves to the same source of disease will often be very differently affected."

He clearly pointed out three types of sores:—
(a) The primary indurated and limited ulcer, followed by chronic enlargement of the inguinal glands and constitutional manifestations. (b) The sore presenting the characters of acute ulceration, the glands in the groin becoming inflamed and suppurating with no constitutional symptoms; and (c) the sloughing sore, with neither inflamed inguinal glands or constitutional symptoms. With respect to the first two, says he, "Anyone carefully considering these differences for the first time might surely say, Why! these are two different diseases. They cannot depend upon the same morbid poison. And this view has actually been entertained by surgeons of very great eminence, and is regarded by some surgeons even of the present day as the only way of accounting for the difference observable in different cases of syphilitic infection. The difference, however, consists not in the kind of poison, but in the kind of morbid processes to which that poison gives rise in different instances. . . One of the causes which determines an inoculated part at once to pass into suppuration appears to be the fact of the syphilitic poison."

Not long before the lamented decease of Mr. Lee, I drew his attention to the apparent discrepancy between his earlier demonstration of the unity of the syphilitic virus, and his later dualistic theories. gave me permission to make use of, or even alter, any of his writings, and I think it is of interest at the present time, when constitutional symptoms are reported as following suppurative primary disease, to remind observers there are two forms of primary suppurative venereal disease, one of syphilitic inoculation upon infection previously acquired, or inherited which may, or may not be followed by constitutional symptoms and the other having nothing to do with syphilis, and not usually followed by constitutional disease. Recently, however, even this form of sore has been credited with toxic consecutive manifestations, and the initial differentiation of primary lesions becomes even more complicated, in the absence of precise bacteriological demonstration, and history in patient or parents.

In 1862 Mr. Hutchinson adduced three cases of acquired venereal disease in patients the subjects of heredito-syphilis. "In none of these cases did the patients suffer from constitutional symptoms. In none is there any proof that the sores were of the indurated type, and in the first two it is certain they were not. As far as they go they favour the belief that hereditary syphilis, if severe, is protective against subsequent contagion, and that its subjects are not liable to contract the indurated form of chancre." (abstr.) Subsequently, in his work on Syphilis, he reports a case under similar circumstances which developed severe consecutive symptoms, and concludes that more well observed facts are requisite for determination. In 1863 Mr. Lee testified to the same immunity hereditarily acquired, which he had in 1854 alluded to as "natural immunity" in individuals or in nations (16).

In 1864 Drysdale's work, in support of the non-mercurial treatment, was the subject of review. debate, and correspondence (17), and in many places Fergusson's later publication of 1846 is mentioned. In face of Drysdale's quotations from both works, the authoritative opinions expressed in that year regarding mitigation of syphilis (per soil or virus) were, modification by previous infection, hereditary influence, by the length of time it has existed in a people, transmission from one patient to another, repressive and preventive regulations in the Services, climate, treatment, age, sex, coexistence of other diseases, temperament, hygiene, and moral influence, both of which latter value Fergusson himself was alive to, as evident in his chapter on "Fever as an Army Disease."

Digitized by Google

Among "the well-known facts of Fergusson," his notice of the "very severe" disease in Lisbon among the Portuguese is referred to. Professor Neumann's later opposition to the "malignancy (?) of syphilis in Portugal" is, probably, not "evidently a slip of the memory excusable in so bulky a work," as Dr. Ogilvie thinks, but founded on the statements of Fergusson, corroborated by Guthrie.

"One side of the case only is argued. And however this may be calculated to influence those who, with Dr. Drysdale, see only a part of the question, we cannot think that he has advanced any evidence upon which he can claim a verdict from those members of the profession who have studied the whole subject, or from those who have read the book of Nature as it lies open for their inspection.

Now, in many parts of the world it has long been ascertained that these men (rank and file) get well of their venereal complaints without mercury, and the reason is probably the same in all countries. He is one who has not improbably been subject to syphilis before joining the Army, or who is not unlikely to have inherited the disease from his parents. Such persons are very much in the same condition as the Portuguese to whom Dr. Fergusson so pointedly

It should be noted, however, that the long-service system in those days permitted such observations and explanations. At the present day it is the youth who acquires syphilis probably for the first time, and though the same condition of hereditary influence may obtain, the difference between his acquired disease in India and at home must be noted, and aggravation accounted for.

In the recently published "Transactions" of the Third International Congress of Dermatology held in London, 1896, the theory of immunity heredith London, 1896, the theory of immunity hereditarily conferred, receives considerable support from Prof. Haslund, confirming Lesser and Kopp (as we have seen only qualified support from Prof. Neisser), and from Prof. Tarnowsky, of St. Petersburg, whose views form the subject of Prof. Neumann's paper in THE MEDICAL PRESS AND CIRCULAR of January 4th last on the "Etiology of Syphilis Maligna." Tarnowsky states that "in syphilis which never enters the gummatous period, and which is even exclusively limited to the initial symptoms, abortive syphilis so to say," parental syphilis has "transmitted a lesser receptivity to the syphilitic diathesis." He refers to thirty abortive dataset in the majority of which one thirty observed cases, in the majority of which one of the parents had suffered.

(2) With regard to aggravation of syphilis among the British troops in Portugal Fergusson did not admit mercury was the only cause in either paper. He advanced the hot climate and intemperance and transplantation of virus from the mitigated disease of the native to the foreigner. Dr. Ogilvie mentions these, but he does not mention the "febrile affections" incidental to the climate, nor does he mention that Guthrie fully agrees with Fergusson in respect of the aggravating effect of "the change from the climate of Great Britain to that of Portugal in the summer with the different mode of life" which "does act most powerfully on our northern constitutions and disposes strongly to inflammatory affections.

In proof of the truth of Fergusson's views the similarity of the aggravated form of disease among British troops invalided home from India was originally adduced by myself.

(3) In Professor Neumann's paper above mentioned, malaria is stated among other co-existing diseases as an aggravating factor. It is also adduced and confirmed in the recent correspondence (18), and long previously was noted by Mr. Lee.

J. Marston (Royal Artillery) especially noted in 1863 the aggravation of syphilis in the Mediterranean, especially at Malta and Gibraltar, in the summer months (19).

It has also been authoritatively noted that syphilis does exist on the Continent in certain places, for instance, cold regions and seaport towns, in fifteenth century intensity. With regard to seaport towns in general, e.g., Lisbon, so often quoted, hygienic defects—overcrowding, have been given as explanation, while another, confirming therefore Fergusson's earlier view, has been the importation or exportation of syphilis into or from different races at such places.

Another factor in aggravation, confirmed in the recent correspondence, is "youth." Also the absence of repressive and preventive or sanitary regulations, not only with regard to prevalence but virulence (20).

Epidemic intensity is another noteworthy expla-The prevalence and virulence of syphilis in 1860 in the Services was noted over the type of disease in the preceding year, as well as over that twenty years previously, in the Pacific station, The authoritative opinions in favour of this and other factors as opposed to mercury expressed then are confirmatory of the independent views recently expressed, that the influence of mercury cannot be mainly responsible for the present aggravated form of disease among British troops invalided home from India.

No one, I suppose, at the present day doubts the mitigating effects of improved treatment in its broad application, but other factors converting mitigation into aggravation, or aggravation into mitigation, must receive due consideration in explanation of the various degrees of intensity met with in individuals, in the Services, and in a people. Nor should it be forgotten that in the past it is to the "meritorious labours of the Army Surgeons" that the most important advance in the therapeutic treatment of syphilis is mainly due, and that their "opportunities of investigation were" and are "better on several accounts than those of private practitioners, who generally soon lose sight of their patients, and never have them sufficiently under their control and observation to render a full perseverance in any method, a matter of certainty.

The Lettsomian Lecture

SOME OF THE CLINICAL ASPECTS OF GRANULAR KIDNEY. (a)

BY SAMUEL WEST, M.D., F.R.C.P., Assistant Physician, St. Bartholomew's Hospital; Senior Physician Royal Free Hospital, &c.

ALBUMINURIA in granular kidney is an inconstant symptom, but possesses special interest in its bearso-called physiological or functional ings on albuminuria.

After eliminating the various recognised causes of

^{(&}quot;) Abstract of lecture delivered at the Medical Society of London on Monday, February 20th 1819.

the presence of albumen in the urine there remains a group of cases in which albuminuria is present with apparently nothing whatever in the previous history or the actual condition of the patient to explain it. It would perhaps be better to describe this as latent, other than physiological, albuminuria, though it is often not so much latent as overlooked. On the whole, I prefer to speak of "albuminuria in the apparently healthy."

In respect of the frequency of this condition the figures given by the different authors vary in their wide limits, but one notes:—1. That the majority of observations upon which the statements are based have been made upon children and adolescents. And those almost entirely of the male sex. 3. That the higher percentages have been obtained by including cases in which very minute traces of albumen were found by the most delicate tests. To commence we may group the cases into two periods, according as they occur before or after 25. We need only consider two forms—(1) serum albumen, which for our purpose, will also include serum globulin; and (2) nucleo-albumen, a mucin-like body which has been till lately confused with mucin. It is by reckoning nucleo-albumen in with serum-albumen that the high percentages of albuminuria have been obtained. There is no single test upon which reliance can be placed to distinguish absolutely between nucleo-albumen and serum-albumen, but the series of tests systematically used in order will suffice to make the distinction quite clearly in most cases.

Mr. Levison undertook some observations for me on 336 healthy persons, of whom 108 were young soldiers; the rest were hospital convalescents. A proteid reaction of some kind was obtained in 136, or 40 47 per cent., and of this serum-albumen occurred in 22 02 per cent., and nucleo-albumen in 18 05 per cent. The amount of albumen in all cases was extremely small, and probably in half the cases would have been overlooked in the ordinary methods of examination. The largest amount in these series was not more than would give a ring of one to two millimetres in thickness with nitric acid. Nucleo-albumen was found alone in nearly one-half of the cases, 18 44 per cent., and this was the same in both the groups, i.e., before twenty-five as well as after twenty-five. No clinical difference could be detected between the cases with serum-albumen and those with nucleo-albumen.

Speaking generally, the significance of this form of albuminuria is entirely different before twenty-five and after twenty-five. What is required is a systematic series of observations in which the same carefully selected tests have been employed, and a sufficient number of cases of the one sex and of the other examined at the different age-periods, because we have not much information of albuminuria in infancy and early childhood.

Statistics show the extraordinary frequency of albuminuria between 10 and 18 years, usually small, but sometimes considerable. There is no proof that masturbation is a predisposing cause; indeed, what evidence there is, is against it.

It is upon cases of adolescents between 18 to 25 that most of the statements as to physiological albuminuria in adults are based, and most of the observations have been made upon young soldiers. The 108 young soldiers whom Levison examined ranged from 17 to 27 years of age, but of these only eight were above 25. A proteid reaction of some kind was found in 51 cases—47.25 per cent. This was due to serum-albumen in 30 cases—27.75 per cent; to nucleoalbumen in 21 cases—19.50 per cent. The effect of exercise is well shown. Thus, morning drill considerably increased the total frequency of albuminuria, but made no difference in the relative frequency of the two kinds of albumen

If we take young adults between 25 to 30, we find that at the Provident Clerks' Life Assurance Association, in the course of the five years 1893 to 1898, 25 cases out of 7,950 were found to have albumen in the urine. This was a percentage well under 1, actually of 0.55. At another office, for a period of ten years, the number of applicants below 30 years of age was, roughly speaking, about 750, and out of these seven only were deferred or rejected on the ground of albuminuria. This gives a percentage of nearly 1. These facts are sufficient to show that at this age-period albuminuria is very unfrequent, and probably stands at its lowest point in life.

After 30, Levison's figures yield an average percentage of 40, and the difference in results is evidently due to the different tests employed. It would greatly simplify matters if we could agree upon a standard test, and the best in my opinion would be Helleos. An amount of albumen, which cannot be shown by Helleos test may, qua albumen, be diagnosed clinically.

Helicos test may, qua albumen, be diagnosed clinically.
In considering the significance of albuminuria it will be well to retain the division into two groups, before and after twenty-five, as we have hithertodone

Albuminuria is common during the period of growth and immaturity, and becomes less frequent when development is approaching completion. Assuming that during the period of growth all the tissues of the body are in a condition of instability and immaturity, it is easy to suppose that very slight causes might disturb their balance, and thus, in the case of the kidneys, albumen might appear in the urine, as the result of causes which would have no effect upon the fully developed or adult organism, or organ.

Now, as regards the boys in whom albuminuria is found, they appear to fall into at least two groups. In one the child appears to be robust and healthy, has a rigid artery, and a high tension; these are the cases which Clement Dukes has recorded as met with so frequently in schoolboys. In the other the children are not robust and healthy, but feeble and pale, and in them the tension is low and the artery not thickened. These two groups probably indicate not only different conditions but different prognosis. In no case is the albuminuria, strictly speaking, physiological; it is always pathological, though not necessarily renal. What we require to know is the course which these cases run in after life. Granting that many, perhaps the majority, ultimately recover, there remains another group to which the patients continue to pass albumen for many years and yet remain in good health, and a third in which signs of renal disease ultimarely develop. Making all allowance for exceptional cases such as these, the significance of albuminuria in early life must for the present still remain doubtful.

Before 25 many cases may be curable; after 25 the chances of renal disease increase rapidly. Conclusions drawn from cases under 25 cannot be applied without consideration to cases over 25.

If we follow out the history of these cases we find, for example, that in Washbourn's series, out of 1,070 cases 38 had albuminuria, that is to say 3.55 per cent. Of these 38 cases 18 were traced. Thus, out of 18 cases 6 had renal disease for certain and 5 more probably, giving a percentage of not less than 33 and possibly of 60. Washbourn calculated that the mortality-rate among these cases for the age was 17.54 per cent., that is to say was nearly double the normal average.

Munn found that out of 25 cases 1 died within the year following the examination, and 4 more died during the subsequent 3 years, while is all the rest the health had obviously deteriorated. In another series of 6,400 adults examined between the years 1877 and 1893, 454 cases of albuminuria were found. Of 137

cases among these in which the urine was examined microscopically casts were found in 31, i.e., in about 23 per cent. Thus in round numbers albumen occurred in about 7 per cent. of all apparently healthy adults, the probability of finding casts in the urine associated with albumen was about 1 in 4. For the first 8 years or so nearly all the cases were traced and the record is remarkably complete; after this many apparently were lost sight of. During those 8 years the total mortality in cases under 40, was 17 per cent., and in cases above 40 30 per cent, a very considerable death-rate for presumably healthy lives. Evidently therefore the albuminuria largely increased

In this class, taking 8 years also, the mortality was higher—viz., 20 per cent. and 50 per cent. respec-

tively

The following table has been calculated out for me by an actuary friend, to snow approximately, as far as the figures permit, the difference in mortality compared with healthy males, and to make the results more obvious they have been taken for difference of two years in age :-

Ages at- tained. 'a)	Rate of Ages following at- (a) year, tained.		Rate of following year.	
3 0	`	501	$370 \dots 197$	
32	1 56 1 06	521	2.64 2.20	
34	3 27 1.11	541	3.74 2.43	
36	3.33 1.16	26½	7.13 2.69	

Without laying any stress upon the actual figures these calculations show how largely the presence of albuminuria raises the mortality as well in those below forty as in those above. We must conclude therefore that for the ages at which Life Insurances are generally effected, i.e., from twenty-five years upwards, the presence of even a trace of albumen in the urine is of considerable significance.

Rabagliati concludes:—
(1) Over 40 reject; (2) under 40 load heavily; (3) in young adults rate up moderately. With the first recommendation I entirely concur. The second is necessary, but the loading might be prohibitive and tantamount to rejection for any age over 30. In respect of the third between 25 and 30 there would have to be a fairly heavy loading, but between 18 and 25 many cases could be safely accepted without any great risk. Each case of this kind, however, must be considered on its merits

The general conclusions to which these consideration lead are these; that the so-called physiological albuminuria is always pathological even if not always renal when the amount of albumen is more than the merest trace, and probably pathological even in these cases when there is but a trace and no good cause obvious.

If renal derivatives are found as well as albumen it must be almost necessarily due to renal disease, and this is in all probability also the case even if no renal derivatives are found in patients in whom the arteries are thickened and the pulse tension high.

ALBUMINURIC RETINITIS.

In its early stage and typical form albuminuric retinitis is characteristic and pathognomonic.

The question arises whether albuminuric retinitis occurs in any other form of chronic renal disease than granular kidney. In acute parenchymatous nephritis and amyloid diseases it is never seen, but it is stated to occur occasionally in chronic parenchymatous nephritis. The changes are usually found in both eyes and are remarkably symmetrical in position.

HÆMORRHAGES.

These generally occur at a later period. There is nothing characteristic about them, for similar hæmor-

(a) Starting with average of those given and assuming uniform increase for eight years.

rages may be seen in grave anæmia and in optic neuritis of other origin. When exudations occur the appearances present a close resemblance to other forms of optic neuritis, thus the vessels may be covered with effusion and the discs be swollen, the edges indistinct and frayed out; yet even in the most extreme cases there is generally something in the appearance of the fundus to suggest the cause of the trouble.

Early as the white patches are, they are preceded and result from still earlier changes in the vessels. The lesions in the vessels have been carefully studied by Brailey and Edmunds, and are briefly described by them as obliterative arteritis leading to inflammatory degeneration of the structures supplied. These changes, Gunn states, begin to be seen usually, between the ages of 40 and 50, but they are not due to old age, i.e., to atheroma, for this does not produce them, but they may occur much earlier in life than this. These changes are really the early changes of granular kidney.

The vascular changes of granular kidney are of great importance in relation to various hæmorrhagic affections of the eye, e.g., hamorrhagic retinitis and hamorrhagic glaucoma. Hamorrhage occasionally occurs behind the eyeball in the orbital chamber, Spontaneous hæmorrhage under the conjunctiva, just as occurs in aged people as the result of atheroma, is

not at all uncommon.

Detached retina is an interesting, but not altogether rare phenomenon in granular kidney. It is in most cases due to an effusion of serum beneath the retina, and not, as might be expected, of blood. Hæmorrhagic detachment of the retina indeed is a The early lesions of albuminuric rare affection. retinitis produce no defect of vision, and even in the later stages it is very remarkable how extreme the eye changes may be without a complaint being made of impairment of sight. Routine examination with the ophthalmoscope will often discover albuminuric retinitis when it is not expected, and will make a diagnosis clear which may till then have been obscure.

When the vision once begins to fail it fails rapidly. Amblyopia is often said to be a common symptom Of toxic retinal amblyopia we know little or nothing, for most of the cases are associated with definite lesions in the retina visible with the ophthalmoscope. Amblyopia of central origin—i.e., non-retinal, is often associated with other symptoms, e.g., hemiplegia. In such cases the amblyopia is also due to lesions of an organic kind. It is not rare when a patient dies of uramia to find the symptoms which appeared to be merely toxic or functional explained by an organic lesion in the brain, viz., small hæmorrhages. In cases of amblyopia in which the defect of sight persists after the uræmic attack is past we must presume there has been an organic In cases of toxic amblyopia recovery lesion. ought to take place in the course of a few hours or less, though instances are recorded in which recovery has been sudden and complete even after four days.

Some clue as to place of origin of the amblyopia may be given by the condition of the pupil. It would be an interesting question to ascertain in what proportion of grandular kidney cases albuminuric retinitis occurs, but that is impossible, for we have not yet the figures upon which a conclusion could be based. I should say that in most cases of granular kidney, if they live long enough, albuminuric retinitis does ultimately develop, but a large number of patients with granular kidney die from other causes, e.g. from hæmorrhage in the brain, and so do not reach the state in which albuminuric retinitis develoos.

Albuminuric retinitis is said sometimes to recover. On this point, I think, some caution must be exer-

cised. Hæmorrhage of course may be absorbed and disappear, whether due to granular kidney or not, but I have rever seen the glistening white patches of granular kidney disappear, though instances are recorded by good observers. It is of course possible where eye changes occur in the course of chronic parenchymatous nephritis that if the primary disease gets well the eye changes also may disappear, but this is not so in granular kidney.

The significance of albuminuric retinitis is always

The significance of albuminuric retinitis is always grave, not only in respect of sight but also of life. The duration of albuminuric retinitis, or of life after its appearance, it is not possible to determine accurately. Speaking generally, the duration of life after albuminuric retinitis has been discovered is short.

Where the patients are in a condition to take the best care of themselves life may be prolonged for some time, but such cases as these are quite exceptional, and speaking generally when albuminuric retinitis is found the patients have not many months to live

Clinical Records.

CASE OF CHRONIC INTESTINAL OBSTRUCTION, RESULTING FROM STRICTURE. (a)

Operative Removal of Cæcum and Portion of Ileum.

By JOHN LENTAIGNE, B.A, T.C.D., F.R.C S.I, Surgeon to the Mater Misericordise Hospital, and to the Children's Hospital.

The patient a girl, æt. 12, came under my care on April 16th, 1898. She was then in a very miserable condition, vomiting frequently and rejecting almost all food, and complaining of constantly recurring attacks of severe pain in the abdomen; the abdomen was greatly distended, and the attacks of pain were usually accompanied by visible peristaltic movements of the intestines, which formed large tumours under the parietes moving slowly in various directions. These attacks would last for one or two minutes after which the patient would be free from pain. The bowels were very constipated, no motion ever coming except after the administration of purgatives followed by enemata. The illness had commenced two years before, and from then the girl had been steadily getting worse up to the date of the first operation.

On April 22nd I opened the abdomen in the median line. Huge coils of intestine, which proved to be the ileum enormously distended and with greatly thickened wall, came out at once. On passing the hand along this enlarged intestine it was found to end in a large mass firmly bound down by adhesions in the right iliac fossa. Owing to the adhesions it was impossible to bring this mass into view, and as the patient was almost moribund be-fore the operation, I decided to give temporary relief by forming an intestinal fistula in two stages, after first emptying the distended bowel by enterotomy. On incising the gut two large basinsful of pea-soup like fæces flowed out, and the intestinal cavity was irrigated and washed out with a stream of warm water; the opening was then closed by silk sutures, and the gut was returned to the abdominal cavity. When emptied and flattened out the intestine seemed to be about four inches across from lower margin to mesentery. My left hand was introduced into the cavity and directed well over to left side; it was then cut down upon and the bowel securely fastened to the opening by a few sutures passing through the parietal peritoneum, muscle and skin. The incision in the median line was closed with three layers of sutures, the two deeper of silk for peritoneum and muscle, and the superficial of catgut for the skin, covered by a layer of celloidin. The small opening on the left side of the abdomen was kept open by a plug of iodoform gauze, and on the third day after operation the fistula was made complete by an incision into the bowel. There was an immediate improvement in the patient's condition. The bowels emptied themselves continuously through the fistula, and the vomiting and attacks of pain ceased almost at On June 27th, as the patient had got into a good condition, and was naturally anxious to be relieved of the annoyance of the fistulous opening, excision of the cecum was performed, with end to end suture of intestine by Kocher's method. The bowels acted naturally four times on June 29th, and almost every day after. There was considerable delay in the healing of this wound, as infection of the silk used in suturing the parieties seemed to have occurred, the silk slowly coming away through a small sinus at the upper end of the wound, and it was not completely healed until October, 1898. The intestinal fistula closed of itself as soon as the bowels acted normally, and on July 12th it had practically closed, neither faces nor flatus coming through it. It was now represented by a firm, clean scar, no trace of the opening existing. The patient was shown to be in excellent health and condition, the bowels acting regularly every day.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.
MEETING HELD FRIDAY, FEBRUARY 24TH, 1899.

The President, Mr. Langton, in the Chair.

EXHIBITION OF CASES.

Dr. Parkes Weber showed a case of recent muscular atrophy supervening long after infantile paralysis. The patient was a boy, et. 17, who suffered from severe infantile palsy at the age of two. About four or five months ago he noticed loss of power in the right hand and wasting in the right thenar muscles. The original disease in infancy affected both right limbs, the right side of the face, and probably also the left lower limb. As a result the whole right lower extremity is wasted and almost completely useless. It was possible that the paralysis of the right arm and right half of the face, from which the patient recovered, were due to a temporary affection of the cerebral cortex (polioencephalitis of Strümpell) occurring simultaneously with the acute anterior poliomyelitis.

Dr. Cahill showed a woman, et. 27, with hypertrophy of the right breast due to pressure of a paralysed and contracted right arm. At the age of nine she had right hemiplegia after diphtheria, and the right arm became spatic and contracted, being firmly flexed and adducted so that the hand pressed on the thorax just above the mamma, and this breast had always been larger than the other. That this was due to the pressure was confirmed by the fact that diminution had taken place since the arm had been kept extended at night by a splint.

The President thought that the breast was not so

much hypertrophied as displaced downwards by the arm. Dr. Caley showed a woman, æt. about 40, suffering from pulmonary fibrosis associated with tabes dorsalis and arthropathy. The patient first came to St. Mary's Hospital in October, 1896, with characteristic symptoms of tabes. As there was some cyanosis of her lips he examined her chest and found signs of pulmonary fibrosis, most marked on the right side, a cavity at the right posterior apex. and bronchiectasis at the right base. She had no cough or other pulmonary symptoms. There was a history of her having attended a hospital for chest trouble at the age of thirteen, and Dr. Caley thought that the chest trouble dated from then. In 1897 she developed

Charcot in tabes Dr. Caley regarded the association of the pulmonary and nervous diseases as purely accidental.

Mr. Bertram Hunt showed a boy, et. 6, suffering from rheumatoid arthritis, with enlargement of the spleen and lymphatic glands. While in hospital suffering from tonsillitis and broncho-pneumonia, the knees and elbows became painful and then swelled. The effusion was not great, and skiagrams showed that the bones were normal. There had been irregular pyrexia,

painless effusion in both knees of the type described by

⁽a) Patient shown at the meeting of the Boyal Academy of Medicine, January 20th, 1899. See page 220.

the temperature sometimes reaching 104° F, progressive ansemia, enlargement of the lymphatic glands in the axilla and groins, and considerable enlargement of the Bacteriological examination of the synovial fluid gave negative results. Mr. Hunt thought that the joint disease had been secondary to tonsillitis.

Dr. WASHBOURN and Mr. ARBUTHNOT LANE showed a woman from whom Mr. Lane removed a tumour growing from the pia mater over the arm area two years ago. The case was recorded in the Clin. Soc. "Trans.," Vol. XXX., p. 154. Permanent paralysis of the right arm had followed the operation, but she was otherwise in good health, and there had been no recurrence of the fits from

which she previously suffered.

Dr. Mowat Biggs showed a young man suffering from factitious urticaria. The patient was a healthy athlete, who had never suffered from urticaria from any of the usual causes, but remarkable unticarial wheals could be induced anywhere on his skin by drawing lines on it with any blunt instrument A white wheal rose on a scarlet back ground, forming an elevation of quite an eighth of an inch. This reached its maximum in five minutes, and faded in the course of an hour. There was not the least itching or discomfort. Pressure alone brought them about. Some cases had been described in which similar wheals were produced by local cold such as that by ether spray, several of them having also paroxysmal hæmoglobinuria, but these were not present in this case.

MYOSITIS OSSIFICANS PROGRESSIVA.

Dr. RAYMOND CHAWFURD (with Mr. LOCKWOOD, of Sheffield) showed a well-marked example of this condition in a boy, æt. 6½. There were no traceable evidences of rheumatism in the family, though the child himself had disease of the mitral valve, which presumably was rheumatic. Injury, as in so many cases, appeared to have been the direct exciting cause at 21 years old. The bony growths for the most part seemed to have originated from the spinous processes of the vertebræ, and to have spread into the retro-vertebral muscles, more particularly the latissimus dorsi and trapezius; the child's back was traversed in several directions by elevated ridges of bone. The fixed curvature of the spine and the rigidity of the cervical muscles gave the child a very characteristic attitude. The upper arms were glued to the sides by ossification of the humeral attachments of the latissimus dorsi on either side. Skiagrams were handed round to show the actual condition of the thumbs and great toes. The shortness of the thumbs was chiefly due to shortness of the metacarpal bones, and their rigidity to synostosis of the first and second phalanges. In the great toes the metacarpal bone was completely united by bone to the first phalanx, and the effort of nature to compensate this condition had resulted in a throwing outward of the ungual phalanx beneath the second toes.

Dr. Leonard Guthrie showed a case of myopathy in a child of 4. The disease appeared to have been congenital. The child had never been able to walk or stand. He could sit up, but easily fell backwards and was unable to rise. All the muscles were extremely weak, but in the arms he could perform most movements, although feebly. In the legs there was almost complete loss of power. There was diminution of both faradic and galvanic irritability, but no definite reaction of degeneration.

Dr. Guthele also showed a boy of 6 with infantile paralysis affecting both arms, and also the intercostal muscles, so that the breathing was purely diaphragmatic.

The legs were unaffected.
Dr. St. Clair Thomson showed a man, et. 36, complaining of dysphagia, and found to be affected with unilateral paralysis of the eighth and bulbar nerves. He had complained of giddiness and deafness for three years, and a year ago he became hoarse and had difficulty in swallowing. On examination his left vocal cord was found to be paralysed. There was no esophageal obstruction. Six months ago his palate became paralysed on the left side, and taste is lost on the back of the tongue on that side. The pulse has been rapid throughout. There was no specific history, but considerable improvement followed a course of mercury and iodide of potassium.

Sir Hugh Beevoe showed a case of chronic rheumatic arthritis in a man, et. 60. It was almost confined to the metacarpo-phalangeal joints in either hand. The fingers were flexed to the ulnar side. This was attributed to the use of his hands in working the large "sweeps of a barge.

Dr. HARRY CAMPBELL showed a case of asthenic bulbar paralysis in a woman, æt. 29, which he believed to be the fourth reported in this country. The paralysis was incomplete, but became much aggravated if the muscles were used. Symptoms showed themselves fifteen months ago when she noticed that she had difficulty of utterance if she sang for a short time. At the present time all the muscles ordinarily concerned in bulbar paralysis were affected by this curious weakness and also the anterior part of the occipito-frontalis, and occasionally there had been loss of power in the arms when they had been raised for a time. The symptoms were always better in the morning after a night's rest. No lesion had been found in the brain in any of the recorded cases. There was no sensory change and the electrical reactions were normal.

Dr. Ormerod said that he had seen an exactly similar condition affecting the upper muscles of the thigh in a

Mr. A. H. Tubby showed a man, æt. 65, suffering from multiple sarcomatous tumours of the skin. The primary tumour was in the upper part of the right side of the scrotum, and was noticed six months before. A second tumour appeared on the left side, and then one under the jaw. Now there were hundreds, some of them of considerable size, all over the surface of the body. The liver was enlarged, and there was some jaundice.

The President referred to a similar case, and commented on the small disturbance of the general health

which they presented.

Mr. Tubby also showed a child with anterior congenital dislocation of the hip. He remarked that this form was more common than usually described, being present in one third of the cases. It was uncertain present in one third of the cases. It was uncertain whether they were intra-uterine dislocations or birth dislocations. In this case he had tried to replace the bone, but had failed, as there was no definite acetabulum.

BRITISH GYNÆCOLOGICAL SOCIETY. MEETING HELD THURSDAY, FEBRUARY 9TH, 1899.

The President, Dr. Macnaughton Jones, in the Chair.

SPECIMENS.

Dr. Bantock exhibited two specimens of fibroid tumour, weighing respectively 61 lbs. and 8 lbs. The first was obtained from a married lady, set. 49, sterile. The case had been under his observation for four years. When first seen, the tumour was about the size of a small fœtal head, on the left side of the uterus, with a good cervix slightly to right of middle line. There were no symptoms demanding interference, and the tumour had been known for eight years. Two years later there were still no symptoms, but about the beginning of 1898 it began to grow, and the menses became more abundant. and irregularly protracted to as much as two to three weeks. The tumour had increased very much, and while it had descended into the left side of the pelvis the cervix had risen until the os could only be reached by the tip of the finger. After securing the ovaries on each side, the broad ligaments were divided and an elastic ligature put round the tumour as low as possible. The peritoneum was then divided all round, and as the tumour was shelled out and raised out of the pelvis, the ligature slipped below the tumour and the slack was taken up. The posterior cul de sac was now opened, the uterine arteries were secured and the whole of the uterus removed. After turning the ligatures into the vagina the peritoneum was closed over, and the abdominal wound closed in two stages. There was very little blood lost, towards which the elastic ligature helped materially. In spite of the

great amount of fat in the parietes, and a very troublesome cough the wound healed well, except just at the umbilicus where it was difficult to keep the edges of the skin

together

No. 2 This was a rapidly-growing pedunculated fibroid springing from the fundus of the uterus by a pedicle from three and a half to four inches in circumference removed from a single lady, æt. 49. There was an enormous plexus of veins in the left side. Having failed to secure the pedicle by ligatures after forcible compression, he was obliged to use the serrenceud after removal of the appendages. The patient was doing well.

Dr. HERBERT SNOW.

CASE I. Vaginal Hysterectomy for Epithelioma of Cervix.—A single woman, æt. 28. Five months previously fell over edge of bath with legs separated. Hæmorrhage three weeks afterwards, followed by the usual symptoms. "Scraping" in a provincial hospital a month before admission. A soft, flattened, pulpy, broad mushroom-like mass of cervix; bled profusely when touched: marked anæmia,

At the operation most of this had to be torn off with fingers before any hold for the volsella could be gained. This on November 25th last. Entirely cicatrised on December 19th. Remains well up to date. By the

microscope, epithelioma

CASE II. Abdominal Hysterectomy for Myoma.—Tumour noticed three months in a rather spare married woman, set. 37. Growing rapidly and causing frequent and

scanty micturition.

At the operation a departure was made from usua methods, by dissecting off a thin layer of the uterine tissue, as well as peritoneum. The advantages claimed for this are smaller risk of wounding ureters. Also preferable when many pelvic adhesions. The plan has the disadvantage of greater liability to hæmorrhage from the uterine veins. This readily controlled, however, by dragging well on the tumour with the volsella. Martin's catgut used for the lower ligatures. Abdominal wall sutured in two layers, catgut and silk. The process of recovery shown by temperature chart.

CASE III. Small Myona removed from Portio-vaginalis,

CASE III. Small Myoma removed from Portio-vaginalis, Posterior Lip, of Woman, at. 47.—Formed a most pedunculated mass, causing much lumbar pain, and profuse vaginal discharge; so simulating malignancy. Only myoma detected. The operation in November, 1897. Now exhibited as showing the fresh appearance of the tissues, as preserved by the formaline process, after the

lapse of time.

toneum.

REMARKS ON DRS. BANTOCK AND SNOW'S SPECIMENS.

Mr. F. Bowreman Jessett said he was pleased to find that Dr. Bantock was becoming a convert to the subperitoneal method of dealing with these myomatous growths. He could not quite understand why he used the elastic ligature, as, even in the very largest cases of myoma, he had never seen any hæmorrhage which could not be controlled by pressure process. Moreover, in his opinion, the very presence of the elastic ligature must interfere materially with the later steps of the operation, whether for complete removal of the uterus or the subperitoneal method of dealing with the stump. Mr. Jessett always found it easy to ligature the uterine artery after the broad ligament had been secured and divided. Mr. Jessett regretted that Dr. Bantock had in his second case resorted to the serrenœud, as on examining the specimen he could not see that there would be any difficulty in ligaturing the uterine arteries and treating the stump subperitoneally.

Referring to Dr. Snow's case. Mr. Jessett had always been able to peel off the peritoneum from the growth and uterus in the front very easily; posteriorly occasionally there was greater difficulty. He could not agree with Dr. Snow that securing some of the uterine tissue was good practice, and he feared the patient would be much more liable to sepsis from the possible sloughing of the tissues. Moreover there must be much more bleeding from the cut surface than would arise from peeling off the peri-

Dr. F. Edge agreed with the views and remarks of Mr. Jessett. His experience, although short, had proved to him the inadvisability of leaving the cervix or any uterine tissue, as was the case with the extra-peritoneal

clamp operation, and as Dr. Snow had advised in his case since it was at present not in their power to decide with certainty whether the growth was malignant or benign. He had had two cases of malignant growth, whether recurrent or arising de novo was not known, in portions of uterus left within twelve months.

Dr. Walter (Manchester) referred to some of the inconveniences and dangers of using the clamp; since he had discarded it he found the mortality of abdominal hysterectomy was greatly reduced. He did not see any necessity for including muscular tissue in the flaps as advocated by Dr. Snow, unless in those cases where the myoma was intra-ligamentous, and in direct contact with

the ureter.

The President asked Dr. Snow if he understood him to say that the operation he referred to was myohysterectomy, If so, he demurred altogether to the leaving of any muscular tissue to cover the stump, and he could see no possible object with regard to the ureters. Often as Howard Kelly's operation had been performed, it was still on its trial as a perfect method as compared with complete removal of the uterus, or pan-hysterectomy. The leaving of the cervical stump was a most important consideration. It involved the possibility of infection from the cervical canal and sloughing of the stump, as well as return or recurrence of disease in the latter. If myo-hysterectomy be performed, he preferred to leave as little muscular tissue as possible, covering the stump carefully with peritoneum alone, and hollowing out as far as possible the subjacent tissue of the cervix. He quite agreed with all that had been said of the now discarded elastic ligature, and believed that Dr. Bantock would before long, with his usual operative skill, bring as large tumours for exhibition removed by the subperitoneal method without ligature.

Dr. Bantock, in his reply, expressed his astonishment that he could have been so misunderstood as he had been by Mr. Jessett, Mr. Edge, and Dr. Walter. The greater part of their criticism was absolutely irrelevant to his remarks. With regard to Mr. Jessett's objection to the elastic ligature he had to say that in the first case it was of the greatest service to him and would always prove to be so when properly used. As to that barbarous instrument—the serrenceud—which was objected to, on the ground—among others—that it caused so much pain, his answer was the words of his patient that very mornning—viz—that she had no idea that the operation could be attended with so little pain. He could not accept the opinion that the sub-peritoneal or intra-peritoneal method was likely to yield the best results as experience had proved the contrary, and it lay between the clamp or elastic ligature with the stump fixed in the parietal wound and total hysterectomy, both of which were extra-

peritoneal methods.

Dr. Snow, in reply, had omitted to mention a third advantage, which had originally suggested the procedure: he had seen the peritoneum torn so that the flaps could hardly be brought together. This could not happen when muscle was included. He could not possibly see how Mr. Jessett could fear subsequent sepsis, if sufficient precaution were taken to asepticise the cervical canal; nor what objection there was to leaving behind a small portion of uterine tissue, as stated by Mr. Edge. Pan hysterectomy should he thought, be reserved for malignant cases, on account of the much greater risks. The case had done so well, that he should certainly be disposed to repeat the method.

COMPLETE REMOVAL OF FŒTUS AND SAC IN A CASE OF ADVANCED EXTRA-UTERINE PREGNANCY.

Mr. Mayo Robson, of Leeds, gave an account of an interesting case of advanced extra-uterine pregnancy, in which he had successfully removed the feetus and sac complete. It is published in full on page 209.

In the discussion that followed:—

The PRESIDENT said that the two important points dealt with in Mr. Mayo Robson's paper were those of the propriety or feasibility of the removal of the sac, and the management of the placenta. With regard to the opinion quoted by Mr. Mayo Robson out of his—the President's—work, the view there expressed was not his own, but that of Mr. Bland Sutton, whom he was happy to see present. On both points, as regards placenta and

sac, in these advanced stages of the pregnancy, authorities were divided, and such a case as Mr. Mayo Robson's was valuable, as showing the advantage of removal of the

Mr. T BLAND SUTTON asked Mr. Mayo Robson how many cases of advanced extra uterine pregnancy he had [Mr. Mayo Robson: About three.] He thought that three were too small a number to generalise upon. There were two quite distinct kinds of sac to be considered; firstly, the sac formed in part out of the broad ligament when the pregnancy was intra-ligamentous; secondly, that formed by the feetal membranes when the tube had ruptured in such a fashion that the feetus passed into the general peritoneal cavity. The latter kind of sac could be removed as a rule, but these cases The latter were very rare; he had seen only one out of sixteen cases of advanced extra-uterine gestation. The feetus might pass out of this sac also; not very long ago he had operated on such a case. Dr. Giles, who assisted him. could corroborate his statement. The feetus was lying quite free among the mother's viscera, and clutched at its mother's omentum during extraction. But when a sac was formed by broad ligament and the child was alive the removal of sac and placenta was one of the most formidable operations in surgery.

BANTOCK expressed his concurrence with Mr. Bland Sutton's views. The first case he saw was at St. Thomas's Hospital, in which it appeared that the fœtus escaped with its amniotic sac into the general peritoneal cavity, and then went on to full time, being alive at the time of operation. The placenta covered in the pelvis on the left side, attached to the left side of uterus, broad ligament and intestines, and any attempt to remove it must have proved disastrous, as an accidental disturbance of a very small portion of its edge caused very troublesome bleeding. He had seen only one case of troublesome bleeding. He had seen only one case of rupture into the broad ligament, and the case showed that the proper treatment was opening the sac, emptying it of its contents, stitching it to the parietes, and draining. He had described one case before the Society, in which he removed the whole sac, containing a large child, as easily as if it had been an ovarian tumour with a broad pedicle. He had brought forward this case to support his view that when the pregnancy occurred in the uterine end of the tube rupture usually took place about or within the thirteenth week, that when it occupied the outer end of the tube it escaped through the mouth of the tube, but that when the middle portion was the seat of the pregnancy it might go on to full time without rupture.

Dr. WALTER pointed out the great difference there was in operating on advanced cases of ectopic pregnancy after the fœtus was dead. To remove the sac under those circumstances was not attended by the same danger as when the feetus was still living.

Dr. F. EDGE said he had had the pleasure of hearing Mr. Taylor deliver the Ingleby Lectures, which marked a step in our knowledge of the subject. In tubo-abdominal cases it was pointed out that the sac and placenta were almost entirely tubal, and that the blood-vessels were ovarian and uterine, and if these supplies were controlled the case was in the surgeon's command.

Dr. ARTHUR GILES thought the discussion would be of permanent value, and it would impress on all present the distinction, hinted at by Mr. Mayo Robson, and unfolded with singular clearness by Mr. Bland Sutton, between the different kinds of sac met with in ectopic pregnancy at term, namely, the feetal sac in the rare cases of abdominal pregnancy, and the sac formed by expanded broad ligament occurring in intra-ligamentous pregnancy. He had a vivid recollection of the case mentioned by Mr. Sutton. He had himself operated in a case of intra-ligamentous pregnancy at the fifth month, and had removed the entire sac. In that case the feetus had evidently been dead about a fortnight; but even with this favourable circumstance, the removal of the sac was not an easy matter, and left a bare space, which could not be covered by peritoneum, on the side and floor of the pelvis. He would ask Mr. Sutton whether such cases, when the fœtus was dead, formed a general exception to his rule that no attempt should be made to remove the sac in cases of intra-ligamentous pregnancy.

The President asked Mr. Bland Sutton what, in his experience, was the relative frequency with which intraligamentary ectopic gestation occurred as compared with the other forms, tubal, ovarian, or interstitial. He believed that true intra ligamentary gestation was very rare. He took it that Mr. Bland Sutton referred in his remarks to such intra-ligamentary gestation, and of the sixteen cases he had seen did he mean that twelve (?) of these had begun as intra-ligamentary, and was he perfectly satisfied of this fact when he operated? The President cordially thanked Mr. Mayo Robson for his paper, and conveyed to him the indebtedness of the Society for the discussion it had given rise to.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF SURGERY.

MEETING HELD JANUARY 20TH, 1899. The President, Mr. R. L. Swan, in the Chair.

ON DISLOCATIONS AND FRACTURES OF THE ASTRAGALUS. Mr. H. Gray Croly read a paper on astragalus dis-

locations and fractures, and gave a history of several very important cases which occurred in his hospital and private practice. One case of fracture of the body of the stragalus was caused by a horse falling on the man's foot, which was caught in the stirrup. Amputation was proposed, but refused by the patient, who subsequently sought admission into the City of Dublin Hospital. Mr. Croly excised the bone, and the man was enabled to resume his work as a groom. In the case of compound luxation of the astragalus forwards and outwards, the bone was completely displaced from all its attachments; the head and neck of the bone protruded. Mr. Croly excised the astragalus immediately. The accident was cised the astragalus immediately. caused by the man jumping from a trap to save himself, the backband having broken; the man landed on his heel; the foot was forcibly inverted; the internal malleolus was completely buried. The patient made an excellent recovery, and can walk as well as ever. The third case was one of complete simple luxation of the astragalus forwards and outwards. The gentleman, who is in his 69th year, was walking along the street, and slipped off the kerbstone into the gutter, violently twisting his foot inwards, from which he suffered intense pain. This patient was treated for eleven days before Mr. Croly was sent for. On examination, as shown by the cast, the right foot was forcibly inverted, the head and body of the astragalus resting on the dorsum of the foot externally; the skin over the head of the astragalus was red and shining; the internal malleolus was completely buried, a deep groove taking its place; there were two sloughs on the outer side of the foot (ashy grey) and a large deep slough on the inner side of the foot; there was no movement at the ankle. The patient's health was much impaired, and Mr. Croly decided to put off operating until the health had improved and the sloughs separated. On March 5th, and about two months after the injury, as the patient's health was much improved, Mr. Croly, assisted by his son, Mr. Henry Croly, excised the astragalus by making an incision over the protruded bone; the superior articulating surface was directed outwards and had completely left its box. bone was seized in a lion forceps; it had contracted adhesions and required some dissection for its removal. Immediately on the enucleation of the bone the muscles drew the foot into its normal position, and a suitable splint, with footboard, was applied. The patient made an excellent but somewhat slow recovery, and he now can walk without the aid of a stick; † extra thickness on the heel and sole of his boot makes up for the slight

shortening; he has a movable ankle but perfectly firm.

Professor E. H. Bennett expressed the thanks of the Academy to Mr. Croly for his most practical and complete communication on the subject.

Mr. LENTAIGNE exhibited a cast of fracture of the astragalus, This particular injury was exceedingly rare. It was a fracture of anterior portion of astragalus, with displacement forwards and outwards of the fractured head of the bone, and was caused by jumping off a car.

Digitized by Google

After an interval operation was allowed. The loose head of the astragalus was found to be completely detached from all structures except by a few threads of fibrous tissue. The head of the astragalus was reduced and the wound closed. The case was still in hospital, and would be exhibited, he hoped, later on.

Mr. W. I. Wheeler mentioned a case of dislocation of

Mr. W. I. WHEELER mentioned a case of dislocation of astragalus backwards, the result of a blow by a cricket ball on the front of foot when in a flexed position. Efforts to reduce the dislocation were unsuccessful; although it was never reduced the patient to this day has a most useful foot. The question of waiting until a slough occurs, or removing the bone, or touching it at all, was very important. It depended on the circumstances. He had seen cases of slight partial displacement which were left alone and the patients had very useful limbs afterwards. If the astragalus were displaced so much as to act as a foreign body he would advise immediate removal.

The President had seen one case of dislocation which was remarkable inasmuch as it bore out what Mr. Croly had said—the apparent facility with which the astragalus could be dislocated by accident. He had made several endeavours to imitate that force on the dead subject, because he had often had occasion to remove the astragulus for aggravated equino-varus in the adult. It is a very successful operation. In this operation he always had to remove the astragalus piecemeal. He had never succeeded in getting the hammer and anvil described by Dr. Hadden. The result obtained by Mr. Croly seemed to show that the foot was almost as good without the astragalus as with it.

Mr. Croly, in reply, expressed as his strong opinion that immediate removal of the bone with careful dressing of the wound was the proper treatment.

CASE OF CHRONIC INTESTINAL OBSTRUCTION.

Mr. JOHN LENTAIGNE exhibited a patient from whom he had removed the cocum and a small portion of the ileum for chronic intestinal obstruction, resulting from stricture at the junction of the ileum and cocum.

This case will be found fully reported in another column under the heading of "Clinical Records."

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, February 25th, 1899.

THE MECHANICAL TREATMENT OF ŒDEMA OF THE SKIN. PROF. FURBRINGER has an article on this subject in the D. Med. Wochensch., 1/99. The treatment mainly consists in subcutaneous drainage by means of soft rubber tubes. The trocar, 5 to 6 mm. is passed through as nearly as possible parallel to the skin surface, and brought out again, so that the space is tunnelled. India rubber tubing about two mm, in length, but not too loosely fitting into the metal trocar is then passed through. In the middle of the tube three holes are punched a few centimetres apart. The tubing is passed until the holes in it are in the punctured canal, when the trocar is withdrawn. The ends of the tube are now placed in a vessel containing fluid. A lightly placed antiseptic bandage keeps it in position. The tubing is soon so firmly gripped by its vital surroundings that scarcely any fluid escapes from the wound opening. Even when in susceptible people the puncture is painful, the pain soon passes off. Two such tubes may, if necessary, be placed near each other, in order to further facilitate the escape of fluid, but more than these are not required. If the patient requires to leave the bed, for a time, the ends of the tube can be clamped. When the time comes to remove the tubing, this can easily be done by cutting it through close to the wound. Upon the whole

the plan appears to be in some respects an advance on drainage by Southey's tubes.

At the Medical Society Hr. Benda showed preparations from a case of

SYPHILIS OF THE LIVER.

The patient had been a woman, æt. 54, who had died in the 2nd internal klinik in the Urban Hospital. She had also had nephritis, ascites, and general ædema. Section showed nephritis on an amyloid base. There was also general syphilis which had led to great changes in the liver. Numerous cicatrices gave an appearance of nessar lobatum thickly strewn with gummatous nodules. There were in addition broken down gummatous nodules on the skull, and several cicatrices on the bones; deep cicatrices at the base of the tongue, no general smooth atrophy, but retraction of the frinulum glottidis; a cicatrix on the external genitals, possibly the remains of the primary sore and smaller cicatrices from a previous papulous syphilide.

Hr. Hausemann showed the ekeletons from two

RACHITIC MICROCEPHALY.

The patients were sisters, who were admitted into hospital on September 22nd, 1897. Both had necrotic sores on the external genitals resembling noma. They died of sepsis after a short stay in the hospital the younger, eighteen months old, on September 23rd, the elder, two-and-a-half years old, on September 27th. The father showed some possible remnants of rickets. The mother was quite healthy. One child, aged five, has a head like the father, but no rickets, and a later born child was quite healthy. The intellectual development of the children that died was said to be normal, but the speech of the elder one was imperfect. There were abnormalities in the kidneys of both children. The changes in the skeleton were so evident that the children were looked upon as microcephalic, both before and after death. The development of the skull was backward, and showed a resemblance to the birdlike aspect of the Aztec's type. Proportion of the head to the remaining parts as in the dwarf skeleton. The brain very backward in development. The signs of rachitis were very general in both skeletons. The disturbances in the brain corresponded to those of microcephaly; the cerebellum was not covered by the cerebrum, so the sulci and gyri were not sufficiently developed, as, for instance, the frontal gyrus present, but not separated from the second sulcus. The temporal lobes were the best developed. The præcuneus and cuneus very defective. He could not determine any connection between the microcephaly and synostosis of the cranial vault. The development of the microcephaly must begin in an earlier embryonic stage, before that of rickets comes into the question, Feetal rickets, according to recent investigations, were not properly rickets. Hyperemia and slight thickening of the bones were not rickets. Cystowicz had examined 100 feetuses and newly-born children, and had never found rickets; neither had the speaker, and even if feetal rickets could be assumed, it could not reach a high development during feetal life, and as the brain developed during that early period there could be no connection. between the two. It should rather be assumed that with congenital microsephaly rachitis had developed that had led to the sympstesis:

He then showed the skull of a 9-year old child with

a premature synostosis that had led to idiocy; but in spite of this there was no microcephaly, there was no limitation of the development of the gyri by compression.

At the meeting of the Society for Psychiatry, Prof. Westphal gave a note on

AN AS YET UNDESCRIBED PUPIL PHENOMENON.

He showed in a number of patients from the Charité partly with rigid pupils, partly with slowly acting pupils, the following phenomena:—If the eyelids are strongly closed and then opened the bulb rotates upwards and outwards, more rarely downwards and inwards. At the same moment narrowing of the pupil is distinctly seen. The process is best seen when the rigid pupil is widely dilated, when the pupil is already contracted it cannot be seen. In health he had only seen the phenomenon in once instance. The speaker described the phenomenon as a co-ordinate movement from the region of the facial upon that of the oculomotor. In a patient with traumatic neurosis the bulbi on closure of the eyes rotated to the side of the wound.

Hr. König asked if the narrowing of the pupil during sleep was produced in the same way?

Hr. Westphal said that in sleep the eyelids were very lightly closed, but here the contraction was only seen when they were energetically closed.

Hr. Jolly said it was a surprising phenomenon that could easily be verified.

At the Society of Innere Medizin, Hr. M. W. Wassermann spoke on

IMMUNITY AGAINST PNEUMOCOCCI.

He said there were many questions still undecided, such as how the anti-bodies get into the blood, and whether at certain times there were more anti-bodies in certain organs than in the blood. He had endeavoured to solve these questions by animal experiment. As a result of his researches he concluded that a special irritation was set up in the medulla of bones by pneumococcus infection, and that there the anti-bodies were specially to be met with. After the fifth day they passed into the blood, where they remained in the serum a long time. The medulla of bones was, therefore, to be looked upon as the place of formation of the antibodies in pneumonia. These experimental results he was able to verify in the case of a man who died on the fifth or sixth day of the disease; the anti-bodies were found in the medulla of the ribs. Parallel with the passage of the anti-bodies into the blood a leucocytosis developed, but he could not determine experimentally if the leucocytes, the place of development of which was also the medulla of bones, transported the antibodies out of the marrow into the blood, and by their destruction set them free in it.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, February 25th, 1899. CHEONIC BEAD POISONING.

HLAVA records a case of some interest from Eiselt's clinic, a few specimens from which were exhibited at the last medical meeting. The patient was a house painter, st. 58, stiffering from "chronic lead intoxication," according to the clinical records, whose symptoms were described as severe painful attacks of colic as in nephrolithiasis; albumen and granular cylinders in urine; hypertrophy of the left ventricle, &c.

The post-mortem revealed large coagula in the abdomen. Behind and below the right lobe of the liver the serous covering of the organ was torn, and from it protruded a nodulated tumour. On cutting into the parenchyma of the liver a large number of hæmorrhagic centres were discovered, while the peripheral surface was white or anæmic; this condition was most marekd in the right lobe, the external surface having a compressed or crushed appearance. The kidneys appeared quite healthy. In the right ureter not far from the pelvis was found a longitudinal hæmatoma. The mucous membrane of the ureters was thickened, and at various spots The left ventricle was concentrically hypertrophied. The large vessels and vena porta were carefully examined for the cause of this bursting of the smaller vessels, but nothing could be found. On closer examination of the parenchyma of the liver white fibrous bands were discovered around the smaller vessels of the organ itself, causing the vessels of the interior to bulge and become varicose. In one place thisaneurysmal condition was beautifully demonstrated by a section. The disease was therefore a multiple aneurysm of the arteria hepatica which explains the serous rupture and clots found in the abdomen.

Eppinger, in tracing this morbid condition to its source, attributed it to mycotic emboli; while Kussmaul and Mayer are inclined to believe in a periarteritis nodosa extending over the entire arterial system; yet strange to say, after careful examination, the aneurysmal condition could not be found in any other vessels of the body outside the liver, though the walls were much thickened.

Alava was inclined to believe in "lues" localised to the vascular system as the remote primary cause of the morbid transformation.

This opinion is sustained by the microscopic appearances as endarteritis obliterans, in the centre of which are to be met with small miliary tubercles resembling the centre of a gumma.

ACOINE.

Acoine is a substitute for cocain, and it is said to be safer, and to give rise to more lasting effects than the latter as an anæsthetic. By the makers it is known as "alkyloxyphenylguanidine." A dose of 0.5 gramme can be borne without any apparent inconvenience, but larger doses are found to produce an escharotic effect on the stomach and bowel, resulting in death.

When applied to the eye of a dog, anæsthesia may be observed for a few days after its application, there being at the same time considerable irritation of the cornea and conjunctiva.

Experiments have been made with another congener, "Acoin C" (or "Diparaanissyl-mono-paraphenetye-guanidin-chlorhydrat") in different grades of dilution which will produce ansethesia from two minutes' duration to many days. From these results it is found that

1 in a 1,000 will last 15 minutes
1 ... 400 30 ...

Digitized by Google

The latter solution irritated the eye, but did not injure it in any way. The other solutions were quite free from irritation, while the eye was perfectly ansesthetic for the operator.

In the form of subcutaneous injections, it was used in the following form:—

B: Acoin, 0.1; Sodi, Chloratis. 0.8; Aq. Distill, 100.0.

This solution was used without any bad effects being observed, while the anæsthesia would last for forty or fifty minutes, after which sensation returned gradually from the periphery to the centre of injection.

The Operating Theatres.

WEST LONDON HOSPITAL.

Two Cases of Appendicitis.—Mr. Bidwell operated on a boy, æt. 18, who had been admitted with symptoms of acute appendicitis. Seven days before admission he had an attack of pain in the right iliac fossa, which was accompanied by diarrhosa and some abdominal distension. The diarrhea continued, and a hard swelling formed at the seat of pain. The temperature was 102, and the tongue dry and coated. As pus was evidently present it was decided to operate at once. An incision was made along the outer edge of the right rectus muscle, the sheath was opened, and the outer fibres of the muscle separated with the handle of the scalpel; the posterior layer of the rectus sheath was then divided, and the peritoneum opened; a few recent and very slight adhesions were found between the abdominal wall and the cæcum. On passing the finger on the outer side of the cæcum a quantity of very offensive pus welled up; this was washed away with a 1 in 2,000 perchloride solution, and the appendix searched for; it was easily found, and brought up into the wound; it was removed after a ligature had been applied close to the cæcum. The appendix showed a large perforating ulcer in one wall, and inside was a concretion about the size of an almond. A largest size rubber drainage-tube was passed to the bottom of the sac and a gauze drain by its side. Another strand of gauze was placed inside the drainage tube to act as a wick, and the rest of the abdominal incision was closed.

The second case was that of a girl, æt. 16, who had been seized with a pain in the right iliac fossa six days before admission. The symptoms had been similar to those in the former case, with the exception that she had suffered from retention of urine for the last four days, which had necessitated the employment of a catheter. In this case an incision was made with its centre two fingers breadth's internal to the anterior superior spine of the ilium on the right side. After dividing the aponeurosis of the external oblique, the fibres of the internal oblique were separated without division; the transversalis muscle being then cut through; adhesions were found between the abdominal wall and a structure which resembled the cæcum, they were, therefore separated towards the outer side with the finger, and the posterior part of the swelling explored, but without finding pus; a needle was then inserted in the centre of the swelling and pus escaped; a free opening was therefore made evacuating about two ounces of offensive pus and two small concretions about the size of grape stones. The cavity was

thoroughly flushed with 1 in 2,000 perchloride lotion. The appendix was found at the back of the sac, and was removed after ligature of its base and of its mesentery. It contained a concretion the size of a cherry stone, and its wall had perforated by ulceration. A large tube was placed down to the bottom of the sac, a gauze wick inserted and the rest of the wound closed with silkworm gut sutures. Mr. Bidwell remarked that both of these cases were unusual by the fact of their having been accompanied by diarrhoa instead of constipation; the presence of retention of urine, too, in the second case was also unusual, and might be explained by reflex irritation of the right ureter from its proximity to the inflamed appendix. With regard to the incision employed in the first case he said the object of separating the fibres of the rectus instead of going through the linea semilunaris was to avoid the chance of subsequent hernia, and this was the incision he had always practised in these cases, and although answering admirably either in cases of large abscesses or in cases of removal of the appendix between the attacks of inflammation it does not appear, he considered, to be suitable to a small collection of pus such as was present in this case because direct drainage is not afforded. The incision practised in the second case answers this requirement. He said there was considerable difficulty in distinguishing the sac of the abscess from the cocum in the second case, because the size and appearance of the abscess sac was precisely similar to the viscus when distended. He thought it wiser to explore the posterior surface of the swelling than to risk opening what might have been intestine; the diagnosis by inserting an ordinary surgical needle could have done no damage even to the gut, and at once demonstrated the pus. He said he strongly recommended the removal of the appendix in these cases unless it should be so placed that its removal might risk disturbing the adhesions shutting off the general peritoneal cavity. Leaving a perforated appendix, he thought, caused the period of convalescence to be much delayed as a sinus persisted for months, and, moreover, had in some cases been followed by second perityphlitic abscess.

Vital Statistics.

The deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 195 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year.

Birkenhead 25, Birmingham 17, Blackburn 16, Bolton 17, Bradford 17, Brighton 16, Bristol 17, Burnley 16, Cardiff 14, Croydon 15, Derby 20, Dublin 27, Edinburgh 26, Glasgow 32, Gateshead 21, Halifax 20, Huddersfield 12, Hull 14, Leeds 18, Leicester 10, Liverpool 27, London 19, Manchester 23, Newcastle-on-Tyne 21, Norwich 15, Nottingham 17, Oldham 20, Plymouth 20, Fortsmouth 14, Preston 28, Salford 27, Sheffield 20, Sunderland 23, Swansea 19, West Ham 16, Wolverhampton 20. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were: -From measles, 1.3 in Manchester; from whooping-cough, 1.4 in Sunderland, 1.6 in Halifax, and 2.3 in Birkenhead; from "fever," 10 in Gateshead; and from diarrhœa, 10 in Gateshead. In none of the large towns did the death-rate from scarlet fever reach 10 per 1,000. The 92 deaths from diphtheria included 40 in London, 8 in Sheffield, 5 in West Ham, 5 in Swansea, 4 in Birmingham, 4 in Liverpool, 3 in Birkenhead, and 3 in Leeds. No death from small-pox was registered in any part of the United Kingdom. in Leeds .

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 1, 1899.

THE ANTI-TUBERCULOSIS CRUSADE.

WE have already expressed the opinion that the movement which has recently been started for the education of the public and the promotion of legislation for the extinction of tuberculosis, may, if energetically worked, prove to be the central epoch in the history of preventive medicine. The scourge of consumption among Caucasian races transcends that of even small-pox in its prevalence and its fatal results, and presents greater difficulties in finding and applying remedies. Nevertheless, there is every encouragement to press forward the movement with enthusiasm and energy because the means suggested are quite within reach if the public can be once thoroughly aroused to the necessity for self protection and persuaded that strict, but not unreasonable, precaution will afford that protection. The first step will be to clear away the ingrained belief that consumption is necessarily hereditary and almost necessarily incurable, and the second step, to establish the belief that it is a purely contagious disease, and that those who are not exposed to the contagium need not and will not suffer from it. The third step, to make it well understood that, if taken in the early stage, consumption is by no meany incurable under proper management. The next duty of the crusaders will be to persuade the authorities, by persistent agitation, of the urgent necessity for segregation of tuberculous subjects in workhouses, asylums, hospitals and orphanages, on board the Queen's ships, and in other places where people congregate under official discipline, and also to promote, by persistent clamour, legislation for this object. Next comes the peremptory

interdiction of the sale of the milk or the meat of tuberculous cattle, and it may be assumed that any attempt to do this will be met by strenuous opposition by dairymen, farmers, and meat dealers, and that considerable expense must be incurred for supervision of these trades, and for bacteriological examinations. reports, and prosecutions. However, the ground has been already prepared for this sort of legislation by the existing safeguards against cattle disease and milk adulteration, and we trust that the extension of the existing system would not be found very difficult-

The crux of the whole problem is the means to be taken to isolate the free population who may be suffering from the disease, and for this purpose the establishment of Consumption Homes on a lavish scale, and the enactment of a variety of coercive regulations have been already advocated.

To every movement for the protection of the community, obstructions are inevitable. are, first, the Christian Scientists, Peculiar People, Anti-Vivisectionists, Anti-Vaccinationists, and suchlike, who yearn for advertisement, and usually for the more material benefits which accrue therefrom. Next, there is the enormous multitude who know or care nothing about anything save the earning and outlay of a daily maintenance pittance, and every one of whom will need education, persuasion and strong pressure before they submit to precautionary measures. Then there are the intelligent working classes who may resist because their breadwinning is endangered by restrictive measures by the boycotting of their little shops, or their possible discharge from work by reason of supposed delicacy. These are really the only persons to be pitied in this connection, and to whom it is essential to make the burthen of sanitation as light as possible. We may hope that, as regards the prophylaxis of consumption all these obstructions can be got over by patient persistance in persuasion. It is necessary, however, to count among the hindrances to reform, another class whose firm repression is essential at the beginning of every sanitary crusadei.e., the Ultra-Sanitarians. We do not wish to cloud the initial difficulties of this movement by entering into details of these propositions. haps the time may come when the nation is willing to pay the enormous tax required for sufficiently accommodative Consumption Homes, and to face the interference with personal liberty which has been suggested. Certain it is that years must elapse before the public mind is prepared for such a change, and for those who desire, as we do to stimulate immediate action, "the least said the sooner mended" on these subjects. But it is necessary to speak now because in this particular instance a number of these gentlemen are already on the war path. frightening off the public from consumption prophylaxis. More suo they want, as soon as possible, a corps of Inspectors to watch every individual who coughs, to interview him, collect his sputum, and submit it to microscopic examination. Then they want a law to expatriate such individual, if found infected, to a Consumption Home (provided by Heaven knows whom

at Heaven knows what cost); and a further law to compel each one to carry a spit-cup in his pocket and expectorate into it at every public place—at church, in the theatre, or in the omnibus. Lastly, they insist in the immediate provision of Homes at the public expense, forgetful of the fact that there are at least-380,000 persons in the United Kingdom now suffering from tuberculosis, and that each one of these, on the ultra-sanitarian plan, must cost someone at least £20 per annum for maintenance, irrespective of the vast original outlay for the sites and buildings for these homes. If the taxpayer were required to pay the whole maintenance charge, it would cost £7,600,000 a year, with a proportionately larger sum if it were found necessary to retain the patient for a longer period than one year. We entreat our ultra-sanitarian friends to "moderate their transports" for a few years, and not subject this great movement to their freezing douche, even, as one of our correspondents suggests, that they may "advocate the ideal in order to arrive at the practical."

FACTS AND FALLACIES ABOUT INSANITY.

THE course of Monday free lectures at Glasgow University this winter is being taken advantage of and is much appreciated. The University is, as all universities ought to be, modernising so as to bring within the limits of its use not only students within its walls, but the intelligent populace outside. One of the latest free lectures has been that of Dr. Yellowlees, of Gartnavel, on "Facts and Fallacies about Insanity." We are not surprised that this lecture was attended by a great number of people, nor that it was received with rapt attention, for as a popular lecturer Dr. Yellowlees is sure to inspire and interest his hearers. With some of his ideas regarded from a critical, and from a strictly scientific point of view, we cannot agree, but with the general principle of his teaching, and the great purpose involved, viz., the education of the general public on the principles which underlie mental health and the conditions which involve mental disease, we have nothing but good to say. It is quite true that, as Dr. Yelowlees observed, the subject of mental disease is now regarded with an interest and intelligence very different from the superstition and prejudice entertained by the public twenty or thirty years ago, but to go further back and to study the subject as it was regarded in Biblical times the solution of all insanities was at once referred to the unseen and the infinite, afflicted ones were regarded as possessed by a dem n or spirit. Even in Palestine to-day a friend of the lecturer informed him that he had seen a lunatic covered with bruises and wounds. When remonstrated with, his keeper said" It is not the man we are punishing, it is the demon, it is that evil spirit that dwells in him." The conviction that insanity is not a disease is a fearful fallacy. We can endorse this statement. The more insanity is recognised as a discuse by all intelligent, right-thinking men and

women, by those who exercise ordinary common-sense the more will the prejudice against its early treatment break down, and the sooner may we expect to seea serious attempt made to grapple with it in its early stages. On this is based our real foundation of the hope we entertain that by-and-bye the preventive treatment of insanity will take a hold of the public mind as a serious and immediate question of practical politics. The next fallacy Dr. Yellowlees pointed out was the fallacy that insanity was a disease of the mind, of the immaterial part of the man, and through this the natural conclusion arose that he was no longer a human being but was on a level with the brutes, and so he was treated accordingly. That this natural conclusion does arise from symptoms in some mental cases is true, but it does not follow as a necessary corollary that these should be deemed brutes. The next point to which attention was drawn in this lecture was that the disorder of the mind was really due to the disorder of the body. As a general statement this will pass, but undoubtedly these are cases of so-called mental disease which some would call mental idiosyncrasy, and which as ageadvances develops and becomes more pronounced, individualistic and erratic. In such it may be simply impossible to demonstrate any disease of the body associated with it whatever, and up till now impossible even to demonstrate any microscopic brain condition to account for it. Certain statements made by Dr. Yellowlees to his audience might be disputed by medical men, but we are by no means desirous to becritical, having regard to the fact that in lecturing to a popular audience too fine a point would preclude their conception of the real crux of the question, at the same time, we should not like it to go undisputed that, if the blood which the brain receives is thin and poor, melancholy ensues. This, for example, as in Dr. Yellowlees' illustration of brain starvation caused by the over-nursing of women, is not borne out by theactual clinical experience of mental disease. Melancholy is certainly prevalent in these cases, but it is nota necessary sequel to brain starvation, or thin and poor blood. It is a curious fact that the same individual, twice or thrice insane, will exhibit the mental symptoms of opposite poles in two different attacks, melancholia in the one case, mania in the other. A different physical condition may not be discovered to account for the contrast, for all our knowledge of the explanation of different mental states as regards blood supply and the cerebral structure is still in the midst of futurity. With what Dr. Yellowlees has tosay of sleep as a most blessed thing for brain health, we cordially agree, and it is very likely, taking his statements not exactly in a literal sense that the manwho lays his head on the pillow by 11 o'clock at night does the best brain work. Undoubtedly, late hours, irregular habits, excitement, irregular, deficient sleep, accounts for much of our indifferent brain work, and, in susceptible cases accounts for much of our mental disease, it may not be in the present generation, but in generations to come.

IS IT DESIRABLE TO BOIL MILK?

An esteemed correspondent, commenting upon the campaign in favour of boiling all milk before consuming it, ventures to call in question "the enormous benefits conferred on the community by the invariable sterilisation of milk before use," and he openly scoffs at "the appalling results which accompany or follow the drinking of that most pernicious and wicked of fluids, raw milk," a state. ment which he believes has unnecessarily created a widespread feeling of insecurity among members of the public. We must disclaim any sympathy with his views, but it is always well to hear the other side. Alluding to the fact that deaths from abdominal tuberculosis in children are becoming more numerous, he points out that the total mortality among children is decreasing. Scarlet fever, typhoid, and a host of infectious diseases are often ascribed to infection through milk. But the mortality from these diseases is less than formerly. Raw milk from tuberculous cows is said to induce tuberculosis in those partaking of it. Can it do this he asks, unless there is a predisposition to tuberculous disease? Sterilised or boiled milk, he admits, is free from this danger, but, he asks, can it nourish the child as well as the raw milk? He goes on to assert that the impoverishment of the bodysoil, induced by complete abstention from milk in a raw state, and by the administration of only the more indigestible and considerably less nutriious boiled article, increases the possible danger of subsequent infection with tubercle in other organs; that it lowers all the bodily powers and faculties out of proportion to the original reason for its boiling. Let those responsible for the supply, he suggests, go to the fountain-head of the evil, test the cows and reject the tuber-But, he urges, even if the milk be tainted, in the long run as much harm as good is brought about by feeding children who are beyond the bottle or breast stage principally upon boiled milk. It not only conduces to the survival of the unfittest. but tends to cause serious deterioration in the persons of the fit. He declares that there is a very marked difference in looks between children given milk only after boiling, and those who are allowed to consume it raw. The first are anæmic, white-faced, and, although perhaps of good size, flabby; the second rosy-cheeked, full-blooded, and full of animal spirits. Nature, he asserts, never intended children to consume her ideal food solely in a cooked state. Its proteids are altered in character, its phosphates are rendered less available for absorption. while modifications of smell and taste indicate the occurrence of other intimate chemical changes. Nature, no doubt, did not surmise that milk would prove an ideal medicine for the growth of tubercle bacilli; but she provided mankind with defences in the stomach, bowel, and blood, quite adequate in healthy children for a successful resistance against the assaults of the ubiquitous, obstinate, but fragile, bacillus, the causa causans of

tuberculous inflammation and degeneration. If the milk is to be boiled, so must the cream be sterilised; and so should butter be only partaken of soon after melting it at or near its boiling point. Hot buttered toast is generally regarded as heavy and indigestible, but, he asks, may not hot buttered toast, sterilised milk, boiled cream, and hot "Welsh rabbit" represent the most innocuous forms in which to consume milk and its products for infants, youths, and adults of our very delicate population? He concludes his criticism by calling attention to the fact (?) that all products made from milk are rendered more indigestible by heat.

If the sole object and aim of medical humanity were to aid and abet the survival of the fittest no doubt one means at our disposal would be to abrogate all sanitary and prophylactic precautions, and to leave the human race to fight it out with the microbes on the principle that the weaker must go to the wall. Rightly or wrongly public opinion favours an exactly opposite course, and the aim of those who practise medicine is to thwart pathogenic influences by every means in their power, regardless of the ultimate effect of this system of "bolstering up the unfit" on the race at large. Unless we are to reverse the humanitarian levers we must continue to advocate the exclusive use of boiled milk and boiled or carefully filtered water. We may, in conclusion, express a doubt, based on extensive experience, as to the alleged indigestibility of boiled milk. Are roast beef and plum pudding rendered less digestible by the process of cooking? Moreover, laboratory experiments do not show any such difference in the action of ferments on boiled and raw milk respectively as our correspondent's statement would lead us to believe, and we are at a loss to know on what ground, chemical, physiological, or clinical, such statements are founded.

Rotes on Current Topics.

The Possibility of Rejuvenescence.

THE maintenance or the recovery of youth has, ever since the dawn of history, been the aim and object of countless generations of thinkers and hopers, probably as a pendant to the philosopher's stone which if discovered would make persistent youth worth having. It would have been more to the point perhaps if these dreamers had included the maintenance of health among the things wished because no one we imagine would wish to prolong indefinitely an, existence associated with the pangs of chronic dyspepsia or the depression begotten of confirmed melancholia. With the advance of scientific knowledge, it is true, human hopes have taken a somewhat different direction, time has discredited the mysterious jumblings of the old alchemists, and experience has discredited the efficacy of baths of blood, and the at-one-time common belief that sleeping with the young had a beneficial effect on the senile, witness the treatment of King David in his old age, and, much more recently, of Catherine II. of Russia.

Even nowadays there is a general, and probably not altogether unfounded, belief that it is injurious for the young to sleep with persons much older than themselves, though this thesis, even if proved, would not, of course, prove the converse. However this may be, there still lurks in the recesses of the human mind a secret aspiration for perpetual youth of which no better evidence is necessary than is afforded by the popularity which for a brief period hallows every new suggestion holding out the promise in however small a degree, of "repairing the irreparable." Mephistopheles having dishonoured the drafts on his bank of youth men now look to science for a solution of the eternal problem, resolutely refusing to admit that science also is bankrupt. Science has done, and is still doing, so much to render life agreeable that one is loth to believe it cannot prolong the life thus rendered the more desirable. The last craze of the kind was one of which the recollection will, let us hope, sooner or later sink into oblivion with the mortal remains of its author, the late Brown-Séquard, who mistook his senile dreams for realities and his aspirations for accomplished facts-His arguments were preposterous, and his methods revolting, but his object was one that secured for him and his measures an outburst of popularity which caused the wise to blush, and over which the frivolous made merry. Such popularity is of its nature ephemeral and the Tarpeian rock is not far from the Capitol. Undeterred by experience others will from time to time hold out mirage-promises to the eager crowd ever willing to acclaim without too closely scrutinising their credentials those who are clever enough to promise compliance with their wishes. Some are fools and some are knaves, but all dealers in rejuvenescence fall into one or other category.

The Law as to Quack Concoctions in France.

An important principle, which may have farreaching effects, was recently established in the law courts in France. A firm of opticians were the proprietors of a glass containing baryta from which they manufactured spectacle lenses. The latter were described as "isometropic," and were extensively advertised as possessing excellent qualities. Dr. Javal, however, of the Sorbonne, having had his attention directed to the claims of the advertisers, commissioned two of his assistants to institute a careful examination of the special glass and of the lenses made from it, with the result that they reported that the difference between baryta glass and ordinary glass was insignificant, that they were not in favour of the former, and that isometropic "lenses" did not offer any advantages to purchasers. Dr. Javal accordingly brought this report under the notice of the French Academy of Medicine, whereupon the firm sued him for £800 damages. But the Court found for Dr. Javal, maintaining that a scientific man might rightly examine and criticise upon public grounds any manufactured article for which special merits were claimed. This

undeniably is a most important principle to have established, and its legality might with advantage be put to the test in this country. If a board of analytical and medical experts were to be formed for the purpose of analysing, testing, and reporting upon the many quack concoctions thrust under the noses of the British public which are guaranteed to cure all the ills to which human flesh is heir, a marvellous work might be accomplished. The public, as it has been proved, are unable to protect themselves in this matter; and the Government have repeatedly refused to act but individual enterprise has now and then been of service, and it is to be hoped that such enterprise will prove its value again. A well-known instance of this was the Harness case, the proprietor of the notorious so-called electropathic belt, had a very short inningsas soon as an inquiry into his business was made public.

"The Latest Sham Diploma."

UNDER this heading we recently discussed the assumption of the title of "Doctor of Refraction" by a Yorkshire chemist, which was granted to him by the Philadelphia Optical College. In commenting upon our remarks our contemporary, the New York Medical News, says: "Really we had thought that our neighbours of Philadelphia were more careful of the ethical economy of their medical educational household than this. We supposed the days of Buchanan were gone for ever. Least of all would we have expected a diploma-selling institution to spring up in the ophthalmological line since our lusty young contemporary of Philadelphia had shown frequent signs of caring especially for abuses in this line of the healing art. This is a matter which deserves looking into. Philadelphia's fair name in medical education has become of late years once more a treasure to her and her professional progeny. Let it not be smirched again by the diploma traffic." Presumably by "lusty young contemporary" is implied the Philadelphia Medical Journal, which recently caused some astonishment among its contemporaries in the States by declining to continue exchanging with them.

A New Form of Writers' Cramp.

ALTHOUGH it is not given to a very large proportion of medical practitioners to see, still less to study a case of writers' cramp it is generally conceded to be a very disabling affection. According to Dr. C. D. Musgrove, however, this is not the only professional disability to which this long-suffering individual is prone. This gentleman, indeed, describes a form of angina pectoris or heart cramp observed in a patient who, having to get through some urgent correspondence in a comparatively short time, suddenly experienced the characteristic precordial oppression, followed by violent palpitation, obliging him to abandon his occupation for the time being. The symptoms subsided in the course of a few minutes, but recurred on his recommencing work. The symptoms appear to have been due in part at any rate to the position of the body while at work under conditions which entailed It is obvious that the great nervous strain. attitude of forward inclination which the ordinary use of the pen entails is unfavourable to the proper play of the thoracic apparatus, respiration in a person writing under pressure becoming shallow and the movements of the diaphragm being interfered with by the abdominal compression. The best way to avoid the occurrence of such attacks is to modify the physical conditions under which they are known to arise. The patient, for instance, should be advised to write slowly and never to hurry, using a high table in preference to a desk, or, if sitting, to be careful to cross the legs. These precautions are specially indicated in the subjects of cardiac disease, and in elderly persons presenting signs of arteriosclerosis.

The Proposed London School for Tropical Diseases.

ALTHOUGH the Seamen's Hospital Society have accepted the suggestion of their committee to found a school for tropical diseases at the Albert Docks, it does not follow that the scheme, if carried out, will meet with the support of the profession. There can be no condoning of the gratuitous insult shown the staff of the 'Dreadnought' at the time that the scheme was formulated. Moreover, Mr. Chamberlain has shown a lamentable want of judgment in not having attempted to arrive at a compromise in the matter. It is obvious that the success of such an undertaking must largely depend upon all the support that the profession can give it-a vital fact which its lay promoters seem to have entirely overlooked. Hence, if Mr. Chamberlain had assumed a diplomatic attitude and had shown that he was prepared to reopen the question of the organisation of the scheme, all might have terminated favourably. But now he has obviously proved himself to be a partisan, with the result that he has probably alienated a great deal of support for the proposed school which otherwise would have been freely bestowed.

A Curious Charge of Malpraxis.

REALLY some patients are very difficult to please. Last week at Bristol a dissatisfied person claimed damages from a dentist and from the practitioner who administered the anæsthetic on the ground that they had removed more teeth than he had authorised, and had left him bleeding and still unconscious with a mouth full of holes. The defendants had an easy task in disproving the allegations of negligence and improper conduct in a professional respect and the jury promptly gave a verdict in their favour. This, however, is sorry compensation for all the worry and trouble of defending an action-at-law and the flimsy nature of the allegations can only exasperate the feeling of resentment. We have heard ovariotomists accused of removing spare ovaries, though it is difficult to fathom the reasons that would theoretically induce them so to do. Decayed teeth are about as useful after extraction as damaged ovaries, so that it would not be easy to suggest a plausible knows how deeply anxious the Prince is to render all

motive for a dentist allowing his zeal to outrun his discretion. The public had better take note that when they place themselves in the hands of a surgeon or a dentist the limits of the operation are left to the operator to fix, in the absence of an express stipalation to the contrary. On the other hand, few surgeons of repute would consent to operate with their hands tied, feeling as they must that if they do not possess the patient's confidence, they had better hold aloof.

The Medical Profession in Germany.

THERE seems to be no lack of medical men in the Fatherland. In Berlin and its suburbs, 2,233 practitioners administer to the needs of the community, or one medical man to every 751 of the population. In contrasting this record with the state of affairs in earlier times, it has been pointed out that there were 191 practitioners in Berlin in 1825, or one to every 1,153 inhabitants, in 1849, 515, or one to 823. Moreover between 1875 and 1885, statistics show that while the Berlin population increased at the rate of 37 per cent., the medical practitioners increased at the rate of 43 per cent. The total number of medical men in Germany amounts to 25,957 at the present time, and of these 15,951 are located in Prussia. The curious fact also is stated that the number of medical men in Berlin alone exceeds the total number of practitioners throughout the kingdom of Bavaria. Still, despite these statistics, it is probably the case that in many parts of Germany medical men are few and far between, owing to the scattered population offering them but little opportunity of making a living.

The Prince of Wales's Hospital Fund.

THE Prince of Wales presided last week at the second annual meeting of the committee of this fund, when the statement of accounts for the past year was presented. The total receipts for the year ending December 31st last, amounted to £39,270, while the expenditure was £34,960, of which the hospitals received £32,500. The expenses, therefore, of carrying out the work were £2,460, or "only seven per cent. of the total expenditure," as the report states. But this item of expenditure compares very badly with the announcement that in the first year the cost of collecting the fund only reached two and a half per cent. A sum of nearly £2,500 seems a large amount to spend in order to collect £39,270, taking into consideration the favourable auspices of the Royal patronage of the Fund. After the accounts, however, had been passed, His Royal Highness said, in reply, "My duties are very easy and light ones." It may seem most ungracious to pass any criticism upon this statement, but, at the same time, with all loyal respect, we venture to assert that the Prince of Wales's Hospital Fund would be much more likely to become a success if it were felt that His Royal Highness did take an active part in its management. Whatever reasons may have existed for doubting that this was the fact have now been set at rest by the Prince's own statement. Everyone

the assistance in his power to the London hospitals, but it must be conceded that his fund has not won the confidence and unanimous approval of the hospital authorities. Until, therefore, this is the case we fear that the fund can never be a success. Rather the policy seems to be of those who pull the wires of the fund to deliberately excite a feeling of hostility in certain hospital authorities, instead of conciliating them by tactful management. The editor of the Hospital newspaper has said that the awards of the fund excited very little criticism last year, and assumes from this that they must have given general satisfaction. But a reference to the annual reports of various hospitals concerned, which are now being published, will show him that he is entirely mistaken.

Cycling Incidents.

Two cycling events of the past week have a special interest to the medical profession, the one from a a scientific, and the other from a social standpoint. The first is that of an Australian champion cyclist, who, twenty-five yards before the end of a carnival race, fell forward in his saddle, and, with his feet still moving with the pedals, reached the winning-post, when it was discovered he was dead. The story appears to be well authenticated, and if so it records another striking instance of the indomitable pluck of athletic man. It shows, moreover, the unerring balance and precision needed in a race, and the instinct that caused the rider, even in the act of dying, to throw himself into and maintain a proper poise. This is the only instance, probably, ever recorded of a race being won by a dead man, and it is said the doctors said he died during the last lap. Medical cyclists will naturally look forward with interest to learning further details of this most tragic affair. The second incident was that of a country surgeon haled before a bench of magistrates for riding a cycle on the footpath. He represented that, as a medical man, he was entitled to take the shortest route to his patient, and that did not happen to lie upon the roadway. His plea was accepted and the case dismissed. generally admitted by the legal profession that, for the sake of saving time, a medical man in an emergency has the right to pass over any private ground, and we believe the point has been settled by various legal decisions. At the same time, it would be well for medical men to avail themselves of such a right, assuming it to exist, only upon occasions of great emergency, on the principle that it is easier to raise than to subdue a storm.

The Perfection of Sanitary Science

RECENTLY, in commenting upon the national scourge of tuberculosis, one of the speakers in a discussion at a Liverpool medical society said that we could not hope for a progressive decrease in the disease equal to that of the last forty or fifty years, because sanitary science had become almost perfect. There is much virtue in a saving clause, and the qualifying term "almost" secures a way of retreat from a position it would be impossible seriously to de-

fend. In many of our towns, small and great, especially in these of older creation, it is hardly too much to say if we adopt the view of not a few practical authorities, that sanitary science, so far from having attained its prime, is in its mere infancy. It may be pretty safely asserted, for instance, that not a single London parish has an intelligible plan of its sewers, a fact which is incompatible with systematic administration. In the matter of house sanitation and construction, moreover, it is certain that an enormous percentage of hygienic defects escape detection. The subject is a large one, and is alluded to here, not in a spirit of pessimism, but with a full recognition of the good that has been brought about in the past, and a confident trust in a future perfection. We simply contend that the day of ideal sanitation is not yet at

The Death-Point of the Tubercle Bacillus. ALTHOUGH it is a truism in the mouth of every-

one who speaks of tuberculosis to say that Koch's famous discovery placed the study of the disease upon a scientific basis, there nevertheless remains much to be learned as to the habitat, the natural history, and the means of propagation of this most devastating bacillus. A most important practical step was registered by Woodhead when he showed that milk could be adequately sterilised by raising it over a water bath to a temperature of 198 degs. F. As everyone knows, the simple boiling of milk suffices to destroy any tubercle bacilli it may contain, but exposure to the degree of heat entailed by that process injures the flavour of the milk. Actual boiling, however, is now proved to be unnecessary, but to determine the exact amount of heat required to sterilise would demand the use of a delicate thermometer. a fact that alone would prevent its adoption to any wide extent in the ordinary household economy. The more logical way of preventing consumption would be to look after the cows that supply the milk, and rigidly exclude all tuberculous animals. To treat the victims of the pestilence in sanatoria at great cost, and to allow the active germs to be distributed broadcast by the butcher and the milkman is to pay an enormous tribute of money and blood to the fetish of vested interests.

Tooth Extraction "a Discretion."

An interesting point lately settled in the Blackpool County Court will probably affect the practice of dentistry for some time to come, if not, indeed, for all the ages. From the evidence it appears that a young lady artist went to a branch of a Dental Association in the town mentioned, and requested a qualified assistant to draw three teeth. She was placed under the influence of gas, and when she came round discovered that the whole of the top row of teeth had been extracted. The defence urged that the plaintiff had left herself entirely in the assistant's hands to do what he thought proper with regard to the teeth. The judge, however, appeared to think otherwise, for he promptly awarded the injured patient a solatium of £30 damages. From this

decision few persons are likely to differ. The case is much on the line of the ordinary surgical operation, wherein the discretion as to the extent of operation procedures is usually left to the judgment of the surgeon. At the same time, where there is likely to be any ground of future complaint, as in the removal of the ovaries or of a great number of teeth, it is well to have a written or attested assent from the patient. If it be clearly proved that a dentist has grossly exceeded his authority, as in the Blackpool case, then the laws of common sense equity demand that a smart penalty be inflicted upon him. Tooth extraction à discrétion by a dentist while one is in a condition of suspended consciousness would be a situation too terrible to be tolerated for a moment.

The L. s. d. of Medical Treatment.

THERE can be no doubt whatever that in the highly complex scheme of life, which it is our pride to speak of as "modern civilisation," money is the mainspring on which the efficient and smooth movements of the vital machinery depend. The rich are able to secure change of air, and to command all the costly resources of modern scientific treatment. The poor, on the other hand, are handicapped by their straitened means, and have, for the most part to turn for medical succour to the charity of private individuals, or of the State. Fortunately, most of our large voluntary hospitals are well equipped with the most effective appliances for the relief of ailing humanity, but that fact simply means that so much money has been contributed out of the pockets of the wealthy. In a word, approach the matter from whatever side we may, the conclusion is forced upon one that curative measures are costly. This £ s. d. aspect of the question is more than ever to the fore in these days of open-air sanatoria, local hot-air baths, Röntgen ray photographs, and the thousand and one recent additions to our therapeutic armament.

Artificial Air.

AT a recent meeting of the French Academy of Medicine MM. Laborde and Jaubert contributed a preliminary note on a certain chemical substancethe nature whereof is for the present kept secret, but which, it is claimed, will by simple contact regenerate air contaminated by respiration; in other words, it absorbs the excess of carbonic acid, water vapour, and organic impurities, at the same time liberating with mathematical precision the exact quantity of oxygen wanting. It is asserted that seven or eight pounds of this substance will enable an adult man to live for twenty-four hours in a hermetically sealed space of small dimensions. It would be idle to speculate upon the manifold uses to which such a product might be put. It will solve the problem of ventilating submarine vessels and of aërating divers, and it would also place the oxygen treatment, at present a very costly fad, within the reach of the poorest and the most economical, seeing that with a drachm or two of the salt twenty or thirty quarts of the gas can at once be produced. Perhaps, however, before deciding the best ways in which we can utilise offered for competition.

the new body it would be wise to await further particulars.

Asphyxia as the Determining Cause of Parturition.

Among the numerons hypotheses that have been put forward to account for the initiation of the parturient process is one which assumes an accumulation in the maternal blood of a surplus quantity of carbonic acid, the effect of which it was alleged, would be to determine uterine contraction. This was an excellent example of the pure unadulterated hypothesis, in that not one of the premises had been verified. Dr. Chambrelent, of Bordeaux, records certain experiments recently undertaken by him with the object of ascertaining whether asphyxia will really provoke expulsive action on the part of the uterus. With this object in view, he cut both the vagi in several pregnant rabbits producing double broncho-pneumonia which caused death in the course of two or three days without labour having set in. He concludes that the presence of carbonic acid in the blood, even in lethal amount, is not of itself the determining factor in the induction of labour.

The Admiralty and the "Conscientious Objector."

THE Admiralty have no sympathy with the "conscientious objector," and they have accordingly issued some stringent orders in regard to the vaccination of children belonging to the men of the Royal Marine corps. One of these orders is as follows:-"Unvaccinated families are not to be allowed to live in barracks, nor are they to be conveyed to any foreign station at the public expense; nor is any unvaccinated child to be allowed to attend a divisional school." This order, it is stated, has caused much dissatisfaction, owing to the heavy penalties it will entail upon any man who may object to having his children vaccinated. But no one but a "conscientious objector" could dispute that the Admiralty have acted with sound judgment in the matter having regard to the interests of the public service, as well as to those under their authority.

The English Local Government Board and the Anti-Vaccinationist Guardians.

THE Local Government Board is in the position of prosecuting certain English Boards of Guardians for refusing to appoint vaccination officers. Two of these Boards have refused because the officer, when appointed, would be obliged to carry the Act into effect without consulting them. But it will be obvious that this point involves the whole case because, if the officer were obliged to ask leave to proceed, the Board would certainly refuse it to him.

The Naval Medical Service.

It is announced that a considerable addition will shortly be made to the Service in order to meet the requirements of the large number of ships building. For the present, fifty new commissions are to be offered for competition.

"Double Pneumonia."

THE regretted illness of Mr. Rudyard Kipling, the inimitable tale-teller, in verse and prose, places in evidence the much greater prognostic significance of double pneumonia over the ordinary inflammatory attack, in which only one lung, and usually only one lobe of that lung, is attacked. Double pneumonia, indeed, is but too often merely a manner of dyingan expression of heart breakdown. Although the lungs are the seat of the obvious manifestation of disease, it is really the organism as a whole that threatens bankruptcy. In persons living at high pressure it often happens that nothing occurs to call attention to the dangerously narrow margin of heart-strength until a trifling cold, associated with a little bronchial catarrh, adds the last straw to the burden which the heart has to bear. Unequal to the additional strain, the right heart yields, and the blood, no longer forced through the lungs, accumulates therein, creating a state of congestion which rapidly merges into inflammation. The progress is almost of necessity from bad to worse, because the heart, which has yielded to a comparatively small strain, will very improbably be enabled to cope with the much greater one implied by the modification in the pulmonary circulation. If there are unsuspected reserves of strength which can be drawn upon, the sufferer may yet emerge from the valley of the shadow of death, but, in general, the breakdown is due to irreparable physiological bankruptcy.

Rip Van Winkle.

ONE of our medical weekly contemporaries has happened across the fact that sham diplomas are being issued wholesale to "Fellows" of the Spectaclemakers' Guild, and to "Doctors of Refraction" of some American quack diploma shop. The two paragraphs which have at length enlightened our contemporary, appeared in the MEDICAL PRESS AND CIRCULAR nearly six months ago. However, it is pleasing to know that the Sphinx has spoken, and that it "has no observations to make beyond this-that the public should be warned that the holders (of these diplomas) are not qualified to practise ophthalmic surgery.' Now that "a Daniel has come to judgment" it may, perhaps, do no harm for us to remind the prophet that the sham diploma of "Doctor in Pharmacy" is being freely disposed of by certain Universities in America and France, and may, at any moment, be put upon the English market by the chemists and druggists. The time is, we fear, coming when genuine Doctors of Universities and Fellows of Colleges will decline to use titles and costumes which can be bought in the open market by druggists, spectacle traders, and such like.

THE Gosport magistrates last week dismissed a police summons against a doctor who rode a bicycle on the footpath, on the ground that a medical man called to an urgent case had a legal right to take the shortest way.

From Pillar to Post.

MISS BEATTY, of Beatty v. Cullingworth notoriety, is desirous of exercising her rights under Section 82 of the Lunacy Act in the direction of obtaining copies of the certificates under which she was incarcerated as a lunatic. The Act says that copies of the document in question can be obtained on application to the secretary of the Lunacy Commissioners, but this official declares that they are not in his possession, while the clerk to the Hackney Board of Guardians, who admitted having the certificates, refused to deliver them up without an order of the Court. The North London police magistrate, however, did not see his way to making the required order, as the Act only authorises application to the secretary of the Lunacy Commission. If Miss Beatty perseveres success will no doubt ultimately crown her efforts, and then?

Antipyrin and Salicylate of Soda.

As a combination of antipyrin and salicylate of soda is very much in use at the present time in the treatment of influenza, it is interesting to note what are their effects in respect of diuresis. The salicylate stimulates diuresis while antipyrin reduces it, even in doses not exceeding one grain of each. Coincidently with this effect on the urinary secretion the salicylate determines some vaso-dilatation in the kidneys with a slight rise in the general blood pressure. Antipyrin also tends to raise the blood pressure, but provokes a vaso-constriction of the renal blood vessels with, as already stated, diminution of the flow.

Influenzal Mortality.

As we foreshadowed last week, the weekly mortality returns of the Registrar-General testify to the prevalence of influenza, the number of deaths attributed to this cause having risen to 74, as compared with 50 during the previous week, and 22 and 21 for the two weeks immediately preceding. The lethal effects of influenza, however, are not to be measured by the mere number of deaths recorded under that head, for it will always be found that there is a simultaneous increase in the proportion of deaths from respiratory diseases, the prevalence and fatality whereof are greatly influenced by the influenzal element.

Vaccination Amendment Bill.

WE think it is wise for Mr. Boulnois, Sir John Lubbock, and the other backers of this Bill to introduce it even though its chances of survival are but small. The absence of such a Bill this session would, no doubt, be made use of by the Antis as proof that their victory of last year is likely to be quietly accepted. Emphatically, it is not accepted, and we are convinced that the mass of public opinion is dead against the conscientious objector clause which this Bill proposes to repeal, and that, sooner or later, Parliament will repent of the decision which a timorous and trimming Government has induced it to arrive at.

Additional Army Surgeons Wanted.

THE Secretary for War has announced, in the memorandum of his Army Estimates, that 18 additional officers of the Royal Medical Corps will be shortly required to supply the needs of the additional 30,000 men whom he proposes to add to the Army.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE LATE PROFESSOR RUTHERFORD.—THE CHAIR OF PHYSIOLOGY.—The funeral of the late Professor W. Rutherford took place on Saturday last. A large number of the medical profession in Edinburgh attended at his late residence as a mark of respect for his great attainments and self-denying life in the cause of scientific medicine, along with the representatives of the Senatus of the University and other bodies, while at least 500 students followed the hearse to the railway station. The interment took place at Ancrum, his native place. A full obituary notice of the deceased will be found in another column.

The Vacant Chair of Physiology in Edinburgh University.—Already various rumours as to those who will seek to fill the place of Professor Rutherford in the University of Edinburgh are flying about. As it is perhaps the greatest of physiological plums the candidates will form quite a host in themselves. We hope that the patrons will take into consideration, whoever may apply, the fact that as the ordinary medical student does not propose to become a laboratory research scholar or a physiological expert, but to practise medicine; and that as Edinburgh University turns loose over the world a large number of new practitioners each year, and only a limited number of scientific physiologists in a decade, a professor in this subject should be cognisant of the physiological requirements of the ordinary general physician, and be thus induced to so frame his course of instruction that the future attendants upon our sick may get the most useful and suitable insight into those sections of the science likely to help them in their practice, not to be obliged to master all the abstruse niceties evolved by laboratory workers, many of whom have never felt a pulse or written a prescription since graduation, and most of which are of value may be to specialists, but have to be forgotten by busy practitioners.

Discontent of Students.—Two assistants are now

DISCONTENT OF STUDENTS.—Two assistants are now conducting classes in the Edinburgh University—the classes of Materia Medica and of Physiology. The class of Materia Medica has been so conducted from near the beginning of the session, and some signs of discontent from the students have become manifest. They complain that, having paid for a professor's tuition, they have

received another's.

GLASGOW UNIVERSITY.—THE VACANT ASSESSORSHIP.—It is expected that there will be a very large attendance, in fact a record one, at the statutory half yearly meeting of the University General Council on April 5th next, at which the members present will be required to fill the temporary vacancy of assessor to the University Court. The friends and supporters of Professor Herkless are greatly disappointed at the turn things have taken, as the appointment is now regarded as lying between Sir James Bell, Bart., and Mr. Copland. Professor Herkless is to address a meeting of members of Council in furtherance of his candidature. As the General Council will have two seats to fill in October the result of the vote in April will be an indication of the relative strength of the opposing forces. Sir James Bell has a large committee, over a thousand, but there are 5,541 names on the Council's register. There is no doubt that a great many names have been sent in to swell the list of Sir James Bell's committee under the impression that he is an almoner of the University, and from the fact that he sa in the Court before, but in truth Sir James Bell wa never a student of the University of Glasgow, and hi

connection with the University Court was due to the fact of his being then Lord Provost of the city of Glasgow. Professor Herkless, on the other hand, is a graduate of the University, a teacher in St. Mungo's College, and has done yeoman service for university improvements when things were in a state of chaos.

Honorary Degrees of the Glascow University.—The Senatus Academicus have resolved to confer the honorary degree of LL.D. on the following gentlemen at the public graduation ceremony on Tuesday, April 18th, next: viz., James Finlayson, M.D., Lecturer on Clinical Medicine, Western Infirmary; Sir Henry B. Irving, K.B., Lyceum Theatre, London; William Jacks, merchant, Glasgow, sometime M.P. for Leith and Stirlingshire, author of "Bobert Burns in other Tongues," &c.; Horace Lamb, M.A., F.R.S., Professor of Mathematics in Owens College, Manchester, author of works on hydrodynamics and infinitesimal calculus; Henry Francis Pelham, M.A., President of Trinity College and Camden Professor of Ancient History, Oxford.

IMPROVED FACILITIES FOR THE STUDY OF MIDWIFEEY.—According to University Jottings, Professor Murdoch Cameron "has set his heart and soul" on the improvement of the very wretched facilities for studying midwifery in Glasgow, and the still more deplorable hospital accommodation for lying-in women. Dr. Cameron has our hearty sympathy in this, and we trust his efforts may meet with the success they deserve, and if accomplished, the proposed institution may not become entirely a family company limited. We also hope that this desirable improvement will not fall through as did those efforts on behalf of Queen Margaret College, which still stands greatly in need of a place for her students to study midwifery and gynecology. At present they have to travel in all kinds of weather from the extreme west to east of the city in order to get the necessary teaching, which is particularly unpleasant for female students in winter.

Parliamentary Aews.

In reply to the irrepressible Mr. Bartley, Mr. Hanbury stated that candidates for admission to the permanent Civil Service and all established workmen in Civil departments are required to have been vaccinated or revaccinated. Customs boatmen must have been vaccinated within seven years. The Post Office requires its employés to have been revaccinated, the latter within seven years, an exception being made in favour of ex-soldiers. The Government declines to interfere with the discretion of the Peabody Trustees in insisting on the children of their tenants being vaccinated. Mr. Hanbury added that persons not less than 10 years of age, who have not been revaccinated within ten years, as before the passage of this Act, be revaccinated free of charge by the Public Vaccinator.

A Bill has been introduced by Mr. Boulnois of two clauses only—"to repeal Section 2 of the Vaccination Act, 1898, such repeal to date from October 1st, 1899."

THE Public Health Acts Amendment Bill was down for Wednesday last, but failed to advance a stage, and therefore stands postponed until March 29th.

therefore stands postponed until March 29th.

WE understand that the Government would be willing to facilitate, possibly even to introduce, legislation having for object the amendment of the Indecent Advertisement Act, and the great obstacle in the path of this much-needed reform appears to be the intrinsic difficulty of drafting such a Bill on practical lines.

An amendment of the law as to constructive murder is the purport of a Bill by Mr. Ambrose. He proposes to give effect to the recommendation of the Criminal Code Bill Commissioners, and the Bill provides that upon a trial for murder no constructive or implied malice shall be imputed to the accused merely because it is shown that the death was caused by him or in the course of the commission or attempt to commit some other felony.

In reply to Lord William Fitzmaurice, the President

In reply to Lord William Fitzmaurice, the President of the Local Government Board said that if he saw any reasonable prospect of making progress with a Bill embodying the clauses relating to the inspection of water supplies by local authorities, he should be quite ready to introduce it.

In reply to Mr. Daly, Mr. G. Balfour stated that it was not at present contemplated to suspend the Muzzling of Dogs Order in Ireland. The total number of cases of rabies throughout Ireland in the twelve months ending December 31st, 1898, was 132, as compared with 162 in the last six months of 1897, while the number of cases in the first six months of 1897, before the Muzzling Order came into operation, was 335.

In answer to Captain Norton, it was stated that the average number of trained nurses in attendance on British soldiers in hospital at Cairo and Alexandria, between September 20th and October 30th, 1898, was 236,

made up of 226 men and 10 women.

In reply to a question by Sir W. Wedderburn, Lord G Hamilton stated that the mortality among coolies employed on the Uganda railway works during 1898 appears to have been about 16 per 1,000 per annum on an average labour force of 12,800 hands. At the port of emigration the labourers are kept, as far as possible, apart from all infection; they are medically inspected before they go on board, where their food, clothing, sanitation, and medical attendance are provided for. There are hospitals at the base and at different points on the works. Medical men and medical subordinates. European and Indian, are provided for the service of these hospitals and of the labourers. At the most unhealthy season of the year nearly 10 per cent. of the labourers were in hospital; at healthier seasons from 2½ to 5 per cent. may be in hospital. The medical report of July last says, "the prevailing diseases are malarial fever, diarrheea, dysentery, liver complaint, scurvy, and ulcers. A complication of the last two generally nec essitates invaliding." Those who are invalided are sent back to India.

Obituary.

EMERITUS-PROFESSOR SIR JOHN STRUTHERS, M.D., LL D., Ex.-P.R.C.S.E.

By a pathetic coincidence Professor Rutherford's teacher and old chief in anatomy, Sir John Struthers, has only survived his former assistant by a few days. For some months past his health had not been at all satisfactory, and nothwithstanding a trip to Norway last summer did not improve; so that when a serious attack of influenza supervened a few weeks ago, the physical weakness produced by his long-continued ill-health could offer little hope of a successful resistance to the malign

effects of this modern scourge.

Sir John Struthers was born in Dunfermline in 1823; graduated at Edinburgh University in 1845; and being attracted towards anatomy, soon became a successful extramural lecturer upon this subject. In 1853-54 he acted as deputy-professor in the University in place of Professor Goodsir during the prolonged illness of that well-known anatomist. Ten years later he was appointed the Crown Professor of Anatomy in Aberdeen University, a post which he held and adorned until 1889, when he retired, owing to a feeling that he was hardly equal, at his age and state of health, for the completely satisfactory conduct of the duties. Since that year he lived in Edinburgh, and occupied his leisure by taking an active part in the management of many of the hospitals in Edinburgh and Leith, and in the business of the Royal College of Surgeons of Edinburgh, of which he filled the President's chair two years ago.

Sir John Struthers was essentially a man of ideas and a worker. Many of the recent reforms in the system of medical teaching in Scotland were adumbrated and insisted on by him long before they appealed to the general mind of the profession. In season and, as some thought, out of season. Struthers preached from the text that medical education should not consist entirely of courses of didactic lectures, but should be largely supplemented by practical classes and tuition. Long before Darwin's views upon evolution were adopted by the teachers in medical schools, or regarded seriously by the public, Struthers advocated their truth with ardour, and did much to render them known and acceptable to the people

of Scotland.

A most persevering, even pertinacious, reformer, Sir John Struthers delighted in exercising his power in this direction upon any institution of which he might have been appointed a manager. He often used to boast of how he reformed the medical institutions in Aberdeen, and of several of the hospitals in Edinburgh and Leith after his retirement. His motives were always logically grounded, and conscientiously believed in by himself, but a certain disinclination to modify his own views upon the advice and opinions of his colleagues rendered many of his efforts of less value, and undoubtedly caused on several occasions some feelings of irritation among those of his professional brethren affected by the proposed changes. No doubt his live-long purely academic associations led latterly to his seeming to be a little out of touch with practising physicians and surgeons. He did good work, however, and his strong advocacy of the benefits which would accrue from the addition of a fifth year for clinical work to the students' curriculum, largely educated, we believe, the members of the profession in the decision later come to that such a prolongation should be decreed. His published works were mainly papers upon anatomical subjects.

PROFESSOR WILLIAM RUTHERFORD, M.D., F.R.C.P.S., M.R.C.S.Eng., FR.S., F.R.S.E.

The change for the better in the condition of Professor Rutherford, which we were able to chronicle in our last number when going to press, unfortunately was interrupted upon Monday, February 20th, by a serious relapse—so serious, indeed, that at 7 a.m. on Tuesday morning this brilliant exponent of physiological laws passed away. His illness commenced with a septic tonsillitis, which went on to abscess formation, but, an intercurrent attack of influenza supervening, his heart evinced grave signs of weakness, so that the appearance of pneumonic symptoms upon the Monday night rendered his

condition quite hopeless.

Born in 1839 at Ancrum, in Roxburghshire, the son of a farmer, William Rutherford was educated first at Ledburgh Grammar School, then at Edinburgh University. A successful undergraduate, he obtained his degree in 1863 with honours, and won a gold medal for his thesis. After filling residents' posts in the infirmary, he acted as Professor Struther's assistant in his anatomy room for a year, the pupil predeceasing the teacher by a few days. After a sojourn at the chief Continental centres of medical science, Rutherford, at 26, became Hughes Bennett's assistant in physiology in the University of Edinburgh, only to be selected four years after for the Professorship in Physiology in King's College, London; an appointment gained by reason of the high qualities of bis published results of original work. He held this post for five years for the left three being Fullerian post for five years, for the last three being Fullerian Professor to the Royal Institute of London as well. At the end of these five years his Alma Mater was inspired to send for him to fill the vacancy caused by the resignation of his former chief, Professor Hughes Bennett. Since that time, from 1874 to 1899, for twenty-five years, William Rutherford carried out the duties of the Chair of the Institutes of Medicine in a masterly manner, and devoted his whole existence to the furtherance of the physiological education of his students. So engrossed was he by the constant attention, deemed by him to be requisite and proper for the observance of his academic obligations, that, though highly fitted by mental endowment for the successful prosecution of original investigation, he waived the personal advan-tages which undoubtedly would have come to him had he so pleased, that he might the more thoroughly and conscientiously fulfil his duty to his students. Notwithstanding this his famous series of experiments upon the action of various drugs upon the secretion of bile and in relation to hepatic functions will remain a physio-logical classic, though the results have, and may still have, to be further modified in the light of more recent researches and improved methods.

William Rutherford was of marked individuality. He appeared to be conceited and supercilious, he was really somewhat sensitive, perhaps self-conscious; but absorbed in his life's work. He was most genial and amusing

socially, in his ordinary work so wrapped up in it that his nervous mechanism became impatient of interruptions or mishaps caused by undergraduate thoughtlessness, or by failure of carefully prepared demonstra-tions. No medical teacher in Edinburgh, except Sir William Turner, in anatomy, could approach him in power of lucid exposition, nor in the succinctness with

which his explanations were expressed.

Apart from his professorial duties almost the only offices he held were those of member of the Edinburgh University Literary Committee, and recently of University Representative upon the Royal Infirmary Board of Management. In the latter position he proved of great service, and performed unostentatiously an immense round of useful work. Possessed of a fine musical talent, he not only was able to render his description of acoustical physiology of the greatest value and interest, but was led by it to found in 1866 the Edinburgh University Musical Society, and constantly contributed songs at the various students gatherings or at meetings of the numerous medical social clubs for which Edinburgh is so noted. It was often said against him that as he could show so little evidence of original work or published writings that his teaching must have fallen behind the times. This was not really so. The time spent by him over the study of and obtaining a complete acquaint-ance with the latest physiological doctrines and results, prevented any great output of written work. Every detailand all the minutic of the complicated and necessary demonstrations required for his lectures were personally supervised and tested beforehand. He lived for his subject, and suffered for his devotion to it.

The appreciation felt for him by his students was evidenced by their proceedings on hearing of his death, A meeting of senior and junior students who had attended his class was held on the afternoon of the day of his death, at which it was unanimously resolved to commission Mr. Hutchinson, R.S.A., to prepare a bust of the late professor to be placed in his old classroom at their expense; while on Saturday 500 students attended the funeral cortege from his house in Edinburgh to the railway station, whence his remains were taken to

Ancrum for burial.

DR. CHARLES JOSEPH ARKLE.

WE regret to have to announce the death from pneumonia, at the early age of thirty-seven, of Dr. Charles Joseph Arkle, F.R.C.P., Assistant Physician to the Charing Cross Hospital and to the Hospital for Consumption and Diseases of the Chest, Brompton. Educated at University College and Hospital, Dr. Arkle held most of the resident appointments, graduating M.D. London in 1887. He was elected to the Fellowship of the Royal College of Physicians only last year. At the time of his death Dr. Arkle was Physician to the Electrical Department and Joint Lecturer on Medicine and teacher of Bacteriology at Charing Cross Hospital.

Correspondence.

We do not hold ourselves responsible for the opinions of our correspondents.

MEDICAL RITUALISTIC MILLINERY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-I have read with humiliation the letters of correspondents to your contemporaries on the great, absorbing, and critical gown question, from which the painful conviction is forced upon me that a considerable number of my confrères feel that their status as gentlemen and as members of an educated profession is to be evidenced by a public display of clothing, and that, to obtain the privi-lege of such display, they are willing to descend to the appropriation of costumes to which they have no earthly title, moral or legal, or by precedent.

I ask, sir, are we scientists or only school girls? Have these correspondents no soul above gee-gaws, or do they suppose that their figuring in gowns, to which they are not entitled, will inspire their compeers with any senti-

ment save contempt for their silliness. One writer claims his gown because of the "financial support" (i.e., his examination fees) which he gave to the London College of Surgeons, and another formulates, with great care, the exact material and the colour of the trimmings which he would like in his gown (when he gets it). Have these gentlemen no shame? What would they think of a lieutenant who masqueraded in major's uniform, or a

THE MEDICAL PRESS.

vicar who showed himself in public in lawn sleeves?

As they are debarred by law from these costumes, I venture to suggest that the dress of an alderman or of a parish beadle may be open to them, and would certainly eclipse the "royal blue with red facings," which one correspondent has indicated as the toga of honour.

I am, Sir, yours truly,

TARTAR-EMETIC.

THE TREATMENT OF INFLUENZA BY SALOPHEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—As it appears that we are in the midst of another invasion of our old enemy, influenza, I should like to draw attention to its treatment by salophen, the value of which seems not to be generally known and appreciated by the profession in this country, although the success that has been attained with it on the Continent is remarkable. It has long been an admitted fact that salicylic acid and its salts are among the most reliable remedies in influenza; but the use of this salt and its compounds when long continued, or when exhibited in large doses, frequently produce symptoms such as vomiting, nausea, headache, buzzing in the ears, or even delirium, which often compels us to abstain from their use, and this before the cure is complete.

Salophen is, I understand, a combination of salicylic acid and acetylparamidophenol which is not decomposed by acid, and which passes through the stomach unaltered, and without disturbance. The intestinal alkaline mucus, however, splits it up into salicylic acid and acetylparamidophenol, but the process is so gradual and slow that the effect of the salicylic acid on the system is much more lasting, and this without any of the disturb-

ances previously referred to.

Salophen has been used largely, and with marked success, by many well-known medical men abroad, such as Drews of Hamburg, Hennig of Konigsberg, Goldschlager, Pierre Marie, Huot, Goldmann, Block, &c.. added to which there is any amount of reliable literature to confirm its merits, especially in the work of Dr. Baque. and in the reports of Privy Councillors Guttmann and Drasche, and Professor Raimondi. This drug first came into note in the treatment of acute articular rheumatism, chronic rheumatism, and allied disorders of a rheumatic and gouty nature, but more recently it has been used with success in the treatment of idiopathic neuralgia, cephalalgia, sciatica, &c., and, indeed, in all ailments where the use of salicylic acid is indicated.

It is, however, as a specific for influenza that I desire now to call attention, and from the evidence adduced there can be little doubt that salophen stands pretty well at the top of the list of all the reputed specifics for the

cure of that disease.

Dr. Hennig, when speaking of influenza, says that "among the remedies applied by me for neutralising neuralgic pain none have proved so efficacious as salophen," and he "recommends salophen most cordially in the nervous forms in which influenza presents itself." Dr. Goldschlager, of the Wieden Infirmary, Vienna, reports that he obtained "some extraordinarily favourable results in treating influenza with salophen." Again, Dr. Drews, of Hamburg, is still more emphatic. He states that "the effect of salophen on the nervous forms of influenza is so favourable as to cause me to declare it, unhesitatingly, to be a specific for the nervous forms of influenza." This statement with regard to its specific action is fully endorsed by Dr. Claus, of Ghent, and other physicians. In the face of this unanimous testimony as to the value of salophen, coming from men whose ipse dixit is above suspicion, and incontrovertible, it is clear

that we are in possession of a remedy that will help us in checking the ravage of this recent scourge to society.

The dose used appears to vary somewhat. Dr. Drews, in violent cases, gives an initial dose of 30 grains, followed by 15 grains about every three hours. In less severe cases 8 to 12 grains will suffice, at the same intervals, and in children from 4 to 8 grains, up to about 60 grains in twenty-four hours. The rapidity with which salophen relieves the pains of influenza is of great importance. After profuse perspiration the patient feels practically relieved of the symptoms but it appears to be generally advisable to continue the remedy for a few days after all the symptoms have disappeared.

Lastly, not the least merit of this preparation seems to be that it is entirely innocuous, and that it greatly reduces the probability of complications, and of the supervention of the dangerous sequelæ of influenza to a minimum. I may, therefore, be pardoned calling attention to it at the present juncture, and shall be glad to know that other members of the profession have met

with the same success by its use as

Yours truly. T. POYNTON WRIGHT. Medical Officer of Health for St. Neots, Hunts.

HISTORY BASED UPON DIET.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,-I see in your issue of the 15th inst., an account of how history is based upon diet. The subject is most interesting and is ably treated, but I doubt whether it is not a rather narrow view to look at the present period of history alone, and to deduce therefrom the theory that, because the foremost nations of Europe happen to be large consumers of flesh, flesh eating is conducive to progress beyond the lower stages. The writer admits, indeed, that the ideal, i.e., of course bloodless diet, is quite sufficient for the highest physical development and for the perfect working of our five senses, the ability to satisfy the needs of present circumstances, the qualities of fear, love and endurance of pain; but he goes on to say that the power of governing. of swaying other minds, foresight and providence and altruistic speculation generally, are only capable of their fullest development upon a diet containing fiesh food. Let us consider a few a diet containing near root. Let us consider a few nations who have governed, philosophised, and influenced the minds of others. Which nations are above all preminent here? Without doubt the Jews, Chinese, Greeks, and Romans. The foundations of the creeds, philosophies, and modes of thought of nearly all the world come from the philosophies and learned speculations of these four. The mass of each of these roots was regestarian up to their best periods. nations was vegetarian up to their best periods. Where are the great animal-eating philosophers beside the Jewish prophets, Buddha, Confucius, Pythagoras, Plutarch, Plato, Socrates and the philosophers? These all either abjured the use of flesh altogether, or ate about a tenth part of what the average Englishman thinks he requires. As regards the statement that climate governs diet, we need only mention that can nibals and vegetarians are found in the Tropics, and that in some parts of China where the climate corresponds to and is in some cases more rigorous than, our own, the people are entirely vegetarian. We believe, that, if only a more general view of the world be taken, the British nation will be seen to be in the van in spite of rather than because of, its flesh-eating habits.

I am Sir, yours truly,

Clare College, Cambridge, February 23rd, 1899. WILLIAM CUMMING.

CHLOROFORM ADMINISTRATION IN CHINA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIE,-We have just received the annexed table of results with our regulating inhaler from Dr. John F. Wales, of Kowloon, near Hong Kong. The quantities of chloroform used appear to have been in excess of what experience has proved to be necessary in this country, but obviously evaporation takes place more freely in hot climates apart from the fact that some surgeons anæsthetise more deeply than others. On the whole, therefore, the results obtained in China compare favourably with those obtained in Europe.

We are Sir, yours truly.

KROHNE AND SESEMANN.

[COPY.]

Cases with Krohne and Sesemann's Inhaler at the Civil Hospital, Hong Kong :-

"", of operation = 16½ minutes.

Europeans - 5 men, 100

Europeans - 2 children, 100 2 women, 2 children = 19.

Resume for November.

Chloroform administered 17 times.

Average quantity = 2 dr = 45 m. (= 6 minims per minute, equal to 1.38 per cent. vapour)

time to produce anæsthesia = 8 min. 8 sec. , of operation = 17 min. 16 sec.

Europeans-6 men. Chinese-9 men, 2 women.

Resume for December.

Chloroform administered 18 times.

Average time to produce anæsthesia = 5 min. $58\frac{1}{8}$ sec.

of operation = $9 \text{ min. } 21\frac{7}{8} \text{ sec.}$

quantity = 1 dr. 45 m. (= 6.8 minims per minute, equal to 1.56 per cent. of vapour. Europeans—2 men. Chinese—9 men, 6 women, 1

Detailed account of cases will be published in the annual report by the Colonial Surgeon, which I hope to forward.

MEDICAL SOCIETY OF LONDON.

Dr. Sidney Martin, at the meeting on Monday evening last, read a paper on "Auto-intoxication and its Relations to the Treatment of Disease." He contrasted infection with intoxication, the former being the invasion of the body by a living germ, while intoxication meant the poisoning of the body by chemical agents, usually the products of activity of the living germ. He described three kinds of auto-intoxication:—(1) of gastrointestinal origin; (2) occurring in the course of chronic disease; (3) occurring in association with disturbed glandular function. He objected to the use of the term auto-intoxication to describe the results of bacterial processes, but admitted that it was very difficult to draw a strict line of demarcation between infection and intoxication. He agreed that some of the symptoms of indigestion might be due to the absorption of certain toxic substances formed in the intestines as the result thereof. He discussed the theories put forward to explain the phenomena of uræmia and diabetes, and criticised Bouchard's view, based on the lessened toxicity of urine in uramia, that the symptoms were due to the retention of poisons in the body. At the same time he admitted that occurrence of peripheral neuritis in diabetes seemed to point to intoxication. He pointed out that most glands had an internal secretion indispensable to the integrity of certain physiological processes or their removal might be followed by the nonelimination of some poison inimical to life. Moreover, excessive activity of certain glands might of itself determine profound disturbances of nutrition.

After some remarks by the President (Mr. E. OWEN), who asked whether rickets was not a form of intoxication of gastro-intestinal origin, Dr. Mott briefly narrated the results of certain researches he had made on the bio-chemical changes associated with general paralysis of the insane. These changes were characterised by a widespread fatty degeneration of the tissues, an effect which he thought might be produced by the presence of cholin. Dr. WASHBOURN agreed that the term auto-intoxication was very misleading, in that on the one hand it applied to the absorption of substances from the intestine, and on the other it denoted certain changes occurring in chronic disease.

The President announced that the Fothergillian prize and medal for 1899 had been awarded to Dr. Monckton Copeman for his work in connection with glycerinated lymph.

Medical Rems.

The Cancer Hospital, Brompton, London.

AT the forty-eighth annual meeting of the governors of this charity held last week the report, which was read by the secretary, stated that during the past year 2,477 new patients were received, 835 being in and 1.642 outpatients, whilst the total number of attendances of outpatients was 13,803. The most modern advances in operative surgery had been noted and introduced into the practice of the hospital, and numerous operations of a serious character, which would have been utterly impossible a few years ago, had been performed with remarkably successful results The valuable clinical experience thus obtained was much appreciated by a large number of British and foreign medical visitors. Much regret was expressed at the untimely deaths of Mr. W. Hughes (secretary) and Mr. Edward Cotterell. F.R.C.S., an able and valued surgeon of the hospital for the past six years. The Committee had appointed, as secretary to fill the vacancy caused by Mr. Hughes death, Mr. Fred W. Howell, of the York County Hospital, out of about 300 applicants, and Mr C. Jarman as assistant-secretary in appreciation of his services for twenty-six years. The report and balance-sheet were adopted and the usual votes of thanks accorded, after which the proceedings terminated.

Gateshead Medical Association. (In affiliation with the Corporate and Medical Reform Association.)

AT a meeting of this Association, held on February 7th, 1899, the following resolution was unanimously adopted:—"That this Association strongly supports the memorial of November 23rd, 1898, signed by 309 practitioners and laymen, presented by the Corporate and Medical Reform Association, Limited, to, and received by Medical Reform Association, Limited, to, and received by the General Medical Council, against 'Illegal Certificates in Departments of Medicine, Surgery, and Midwifery,' now permitted by the Council in a department of midwifery, and followed by opticians in a department of surgery, and thanks the direct representatives, Mr. G. Brown, Mr. Victor Horsley, F.R. S., Dr. Glover, Dr. W. Bruce, and Sir W. Thomson, and also Sir C. Nixon, Dr. Bennett, and Dr. Tichborne, for their support of the following resolution moved by Mr. G. Brown and seconded by Mr. Horsley: 'That a Special Committee be appointed to consider and report at the next session of the Council all cases of alleged infringement of the of the Council all cases of alleged infringement of the Medical Acts by persons who profess to examine candidates in medicine, surgery, or allied subjects, and to grant certificates or diplomas testifying as to proficiency in any branch of medical or surgical science.' And that copies of this resolution be sent to the medical Press, and to the representatives above mentioned."

Royal Free Hospital.

THERE was a large attendance last Wednesday at the sevent -first annual meeting of Governors and friends of this charity, the Hon. Mr. Justice Bruce presiding. In moving the adoption of the report, the chairman pointed out that the work of the hospital was being carried out in the most efficient manner in all the various departments, and the committee considered that the time had come when a commencement should be made in carrying out the urgently needed building improvements referred to in the report, viz., (1) the alterations and additions to the ward lavatories, sculleries, and bathrooms; (2) better accommodation for the nursing staff. With regard to the latter, the visitors who inspected the hospital on behalf of the Prince of Wales's Fund, strongly recommend the carrying out of these improvements The total cost of these works, as now estimated by the architect, is £8,500, towards which the sum of £2,870 is available. Mr. Charles Burt, chairman of the weekly board, said that as one of those who had during the past year visited many hospitals and other institutions as a epresentative of the Prince of Wales's Hospital Fund,

he was only too conscious of the need for the improved sanitary arrangements, and the additional accommodation for the nursing staff referred to by the chairman. The Earl of Stamford was elected to fill the vacancy occasioned by the death of the Earl of Lathom, and the election of the Committee of Management and auditors, and votes of thanks to the various committees, medical and other officers, concluded the business.

St. Thomas's Hospital.—House Appointments.

THE following gentlemen have been selected as House Officers from Tuesday, March 7th, 1 99.

Officers from Tuesday, March 7th, 1 99.
House Physicians—G. B. Thwaites, L.R.C.P., M.R.C.S.; (Extension); E. A. Gates, L.R.C.P., M.R.C.S.; A. E. Stevens, M.B.Durh., L.R.C.P., M.R.C.S.; and H. D. Singer, M.B.Lond., L.R.C.P., M.R.C.S. (Extension).
Assistant House Physicians—E. H. Ross, L.R.C.P., M.R.C.S., and H. C. Thorp, M.A., M.B., B.C.Camb.
House Surgeons—S. O. Bingham, L.R.C.P., M.R.C.S.; E. M. Corner, M.A., M.B., B.C.Camb., B.Sc.Lond., L.R.C.P., M.R.C.S.; J. A. Barnes, L.R.C.P., M.R.C.S.; and J. E. Kilvert, L.R.C.P., M.R.C.S.

Assistant House Surgeons - H. J. Phillips, L. R.C.P., M.R.C.S.; P. W. G. Sargent, M.A., M.B., B.C.Camb., L.R.C.P., M.R.C.S.; S. A. Lucas, L.R.C.P., M.R.C.S.; and H. T. D. Acland, L.R.C.P., M.R.C.S.

Obstetric House Physicians.—(Senior) R. H. Bell, M.A., M.B., B.C.Camb., L.R.C.P., M.R.C.S., and (Junior) S. H. Belfrage, M.B.Lond., L.R.C.P., M.R.C.S. Ophthalmic House Surgeons.—(Senior) J. S. Hall, L.R.C.P., M.R.C.S., and (Junior) T. Hoban, L.R.C.P.

M.R.C.S.

Clinical Assistants in the Special Department for Diseases of the:—Throat—W. C. Ambrose, B.A.Camb., L.R.C.P., M.R.C.S. (Extension), and E. C. Bourdas, L.R.C.P., M.R.C.S. Skin—H. M. Scaping, B.A.Camb., L.R.C.P., M.R.C.S. (Extension), and J. Gaff, L.R.C.P., M.R.C.S. (Extension), and J. Gaff, L.R.C.P., M.R.C.S.

Clinical Assistants in the Electrical Department.-H. N. Goode, L.R.C.P., M.R.C.S. (Extension), and A. Bevan, LRCP., MRCS

The Irish Schools' and Graduates' Association.

ST. PATRICK'S DAY falling on Friday this year, the St. Patrick's Festival Dinner of the Irish Medical Schools' and Graduates' Association will be held at the Café Monico, Piccadilly Circus, on Saturday, March 18th, at 7.15 p.m., the President, Sir William Thomson, of Dublin, in the chair. The Association will have the bushin, in the chair. The Association will have the honour of entertaining as the guest of the evening a distinguished Irishman, General Sir George White, V.C., G.C.B., G.C.S.I., G.C.I.E., the Quartermaster-General. As a very large attendance is anticipated, members should make early application for dinner tickets to the Hon. Secretary, P. J. Freyer, 46 Harley Street, W.

The Middlesex Hospital.

THE new laboratories in connection with the Middlesex Hospital Medical School, we understand, are now completed, and are equipped with all the best modern appliances for the purpose of instruction and original research. A conversazione will be held on the evening of March 15th in the new buildings, when many objects of interest will be exhibited.

Mortality in Foreign Cities.

The following are the latest official returns, and represent the last weekly death rate per 1,000 of the several populations':--Calcutta 38, Bombay 98, Madras 42, Paris 21, Brussels 21, Amsterdam 13, Rotterdam 18. The Hague 19, Copenhagen 22, Stockholm 26, Christiania 25, St. Petersburg 27, Moscow 27, Berlin 17, Hamburg 15, Dresden 16, Breslau 30, Munich 22, Vienna 24, Prague 23, Buda Pesth 25 Trieste 33, Rome 20, Venice 28.

Apothecaries Hall of Ireland.

THE following candidates have passed the recent examinations for the License in Medicine, Surgery, and Midwifery :-

Midwifery:—
Physiology—S. Adye, Curran, and L. J. Farrell. Anatomy—S. Ale Curran and A. J. Barnes. Materia Medica—A. J. Barnes. Pathology—W. P. Hardine. Surgery W. W. Feris. Midwifery W. W. Feris. Ophthelm c Surgery W. W. Feris. Completed Third Professional W. P. Harding.

The following have passed the L.A.H.
F. G. Adye Curran, W. P. Delahunt, J. D. Power, M. P. O'Brien, and J. J. Abern.

Rotices to

Correspondents, Short Tetters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTE DE MARILLAC.—We are unable to comply with your request for publication, partly on account of the inordinate length of the communication and partly because the enterprise, at this stage, does not present any particular interest.

F. DEAS (Merton). - Your cases are marked for early insertion.

CHIRURGICUS.—A mixture of soap and glycerine makes a very good lubricant for catneters and the like provided the soap does not comprise an excess if alkali. An alternative suggestion is to make use of the following:—Gum tragacanth, 25 parts; glycerine, 10 parts; solution of carbolic acid (1 in 100), 30 parts; mix and rub down without heating. This has the consistency of cold cream and is re-dily soluble in water, thereby greatly facilitating the subsequent cleansing of instruments.

DR. E M. COSCRAVE.—We hope to have space for your paper on "The Treatment of Tuberculosis at Falkenstein" in our next.

"News Indexed!—We learn from the Globe that men who work in compressed air are liable to a new malady called 'caisson,' or compressed air disease, and Dr. Thomas Oliver traces it to increased solution in the blood of the gases met with in compressed air, and the liberation of these wases after the person escapes from the compressed atmosphere."—Bravo, Dr. Oliver!

DR. S. A. T. - Will receive a private note so soon as the necessary inquiries are complete.

MR. G. J. WILSON.—One cannot always form a correct opinion upon matters on the surface Please supply us with fuller data and we will then carefully consider and report.

MES. S. F. W.—Will be able to get the surgical appliance needed in her case of Mesers. Pope and Plante (recently removed from Regens Street to 39 Old Bond Street, London), who make a specialty of it.

INFLUENZA SET TO MUSIC. OUR "special correspondent," whose letters on Continental Health Resorts are read here with considerable interest, tells that among the musical attractions at Nice last week was a grand concert at which was performed a spirited overture, composed by the Grand Duke Michael of Russia, and eatitled "Influenza." The overture is said to have been written when it author was suffering from influenza and has considerable orchestral merit. The audience received the composition with enthusiasm, as it naturally would from a Grand Duke of Russia, but nothing is said of its effects on the microbe. effects on the microbe.

Meetings of the Societies and Tectures.

OBSTETRICAL SOCIETY OF LONDON.—8 p.m. Specimens will be shown by Mr. Bland sutton, Mr. Targett, and others. Mr. A. Doran (President): Inaugural Address. Paper:—Dr. C. H. Roberts: A second Case of rimary Carcinoma of the Fallopian

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Mr. B. G. A. Moynihan: The Anatomy and Surgery of the Peritoneal Possic. (Arris and Gale Lecture)

MEDICAL AND SCIENTIFIC SOCIETY OF THE CATHOLIC UNIVERSITY.—8 p.m. Inaugural Address by Dr. MacArdle.

THURSDAY, MARCH 2ND.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road).—8.30 p.m. Mr. D'Arcy Power: On Vanishing Tumours.—Mr. B Gardner: A New Ether Inhaler.

IIR TUMOUTS.—Mr. B Gardner: A New Ether Inhaler.

Neurological Society of Lordon (11 Chandos Street, W.).—

8.30 pm. Clinical Evening. Dr. F. E. Batten: Muscular Atrophy in a Child.—Dr. T. D. Savill: Epileptiform Seizures of probable Vaso-motor Origin. Dr. H. A. Caley: Syringomyelia with Sudden Increase of Symptoms.—Dr. W. Harris: Heemorrhage into the Spinal Cord (? Syringomyelia).—Dr. J. H. Bryant: Paralysis Agitans following Typhoid Fever in a Man. et. 31.—Dr. Stansfield: Epileptic Insanity associated with Mastoid Disease, Operation, Relief of Mental Symptoms. And other cases.

British Balnedogical and Chimatological Society (20 Hanover Square, W.).—3.30 p.m. Papers:—Dr. D. Kerr (Bath): Treatment of Disease by Heat.—Dr. Hedley: The Therapeutics of Heat.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m. Dr G.V. Poore: The Earth in Relation to the Preservation and Destruction of Contagia. (Mileoy Lecture.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).- 4.30 p.m. Mr. M. Dockreil: Cases of Telangiectasis and Vascular New Growths.
FRIDAY, MARCH 3RD.

WEST KENT MEDIC-OHIEUEGICAL SOCIETY (Royal Kent Dispensary, Greenwich, Road, S. 8).—8.45 p.m. Clinical Cases:—Dr. McCann and Dr. Ezard: Notes with specimens of (1) a Case of Dermoid Cyst of Ovary, simulating Extra-uterine Pregnancy; (2) a Case of Parovarian Cyst of Unusual Size.—Mr. Ernest Clark: Bye Cases (Living and Pathological).—Dr. Toogood: Cases from Lewisham Infirmary.—Dr. Scholefield: Clinical Cases.

WEST LONDON MEDICO-CHIRUBGICAL SOCIETY (West London Hospital. Hammersmith, W.).—8.15 p.m. Clinical Evening Cases will be shown by Dr. S. Taylor, Mr. E. Pollock, Mr. McA. Ecclee, and others.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square. W.).—5 p.m. Cases will be shown by the President, Dr. De H, Hall, Mr. Bowlby, Dr. E. Law, Dr. St. Clair Thomson, and others.

ROYAL COLLEGE OF SUBGEONS OF ENGLAND.—5 p.m. Mr. B. G. A. Moynihan: The Anstomy and Surgery of the Peritoneal Force. (Arris and Gale Lecture.)

MONDAY, MARCH 6TH.

ODONTOLCGICAL FOCIETY OF GREAT BEITAIN.—Mr.C. S. Tome: F.R.S. "A Remarkable Diseased Tooth," and Mr. F. T. Panl, M.D., F.M.C S. "A Contribution to the Histological Study of Dentine." Casual Communication, by Mr. Ashley Barrett.

Vacancies.

Bristol City Hospitals.—Resident Medical Officer for the Ham htreet Fever Hospital. Salary, £100 per annum, with board, lodging, and washing. Applications, before March 18th, to Dr. Davies, General Medical Superintendent, Fublic Health Offices, Bristol. (See advt.)

Gorey Union.—Trained Night Nurse. Salary, £30 per annum, with £23 extra in lieu of board. Applications to Clerk of Union. (See advt.)

(See advt.)

(See advt.)

Manchester Royal Infirmary and Dispensary.—An Aural Surgeon and an Assistant Surgeon on the honorary staff. The former must be a graduate of a University of the British Isles; the latter must be a F.B.C.S. (See advt.)

University of Glasgow.—Chair of Pathology. The normal salary of the Chair is fixed by Ordinance at £1,100 For particulars as to applications, see advertisement in another column. Weston Super-Mare Hospital.—House Surgeon; unmarried. Salary, £60 per annum, with board and residence in the hospital.

Appointments.

BLATHERWICK, H., L. R. C. P., Lond. M. R. C. S., Medical Officer to the Dulwich Sanitary District of St. Giles, Camberwell.

CAMERON, A. F., M. B., C. M. Edin., Senior Assistant Medical Officer by the Sheffield Board of Guardians.

DE BEAUVAIS, B. N., L. S. A., Medical Officer, to the Milton Abbot Sanitary District of the Tayistock Union.

DICKEY, A. A. G., M. D., L. R. C. S., L. M. R. C. P., Medical Officer to the Colne Sanitary District of the Burnley Union.

DUKR, A. W., Col., M. D. Irel., L. R. C. S. Irel., Principal Medical Officer to the North-Western District at Chester.

FEYER, R. A., M. B., C. M. Edin., M. Edical Officer to the Hoxton New Town Sanitary District, Parish of St. Leonard, Shoreditch. FRYER, R. A., M.B., C.M. Edin., Midical Officer to the Hoxton New Town Sanitary District, Parish of St. Leonard, Shoreditch.

Gabbett, H. S., M.D. Dubl., M.E.C.P. Lond., Pathologist to the Princess Alice Hospital, Eastbourne.

Hanly, John Joseph, M.A., (R.U.I.), Medical Officer to the No. 2 Sanitary District of the Shepton Mallet Union.

Jacob, F. H., M.B. Lond., M.E.O.S., L.R.C.P., House Physician to the Nottingham General Hospital.

Kemper, Gilbert, M.D., E.S., Dunelm, M.R.C.S., L.R.O.P. Lond., Honorary Surgeon to the Salisbury Infirmary.

Mann, F. W. S., L.R.C.P. Lond., M.E.C.S., Medical Officer to the Revesby Panitary District of the Horncastle Union.

Murhay, K. W., L.R.C.P. Lond., F.E.C.S., Honocary Surgeon to the Northern Hospital, Liverpool.

Rawlings, J. D., M.B. L. Ind., L.R.C.P., M.R.C.S., Medical Officer to the Northern Sanitary District of the Dorking Union.

Roche, Antony, M.B.C.P. Irel., Examiner in Medical Jurisprudence and Public Health to the Royal University of Ireland.

Stuart-Low, William, F.R.C.S. Egg., Assistant Surgeon to the Hospital of St. Francis, New Kent Road, S.E.

Whittome, H. M.D., C. M. Edin., Assistant Physician to the Hospital of St. Francis, New Kent Road, S.E.

Births.

Cole.—On Feb. 23rd, at 11 Surbiton Road, Nottingham, the wife of George Cole, M.R.C.S., L.R.C.P., of a daughter.
GRIFFITHS.—On Feb. 23rd, at Egerton, Cheltenham, the wife of Hugh St. D. Griffiths, L.R.C.P., J.R.C.S.Edin. of a son.
Wyborn.—On Feb. 24th, at 204 Camden Road, London, N., the wife of W. E. Wyborn, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

HUTTON—ATTHILL.—On Feb. 23rd, at Monkstown Church, Dublin, Hugh Hutton, of 118 Summer Hill, Dublin, to Maud, youngest daughter of Lombe Attnill, M.D., of Dublin.

Peaths.

- ABKLE.—On Feb. 22nd, at 66 Wimpole Street, London, W., from pneumonia, Chas. J. Arkle, Assistant Physician Charing Cross Hospital, M.D., F.R.C.P., aged 37.
 BASS.—On Feb. 24th, at 9 Upper Wimpole Street, London, W., Frederick Bas, M.D., F.R.C.S., Assistant Surgeon to the Westminster Ophthalmic Hospital, aged 47.
 TERRY.—On Feb. 16th, at his residence, 35, Grasvenor, Bath, John Terry, M.R.C.S. Eng., and L.S.A., aged 77.

Johannis" NATURAL MINERAL WATER LITHIATED

Contains one grain of added Lithium Bicarbonate to each small bottle.

So much importance is attached to the action of Lithium Salts as solvents and eliminants of uric acid, in the numerous maladies referable to the uric acid diathesis, that it is of the greatest consequence the Lithium Waters in use should contain a definite and suitable quantity of a Salt of Lithium, and that this should be authoritatively guaranteed.

The Johannis Springs Company, acting under eminent medical direction, have undertaken to supply precisely the kind of Lithium Water needed for continued consumption as a table water. The amount of Lithium is constant, and the quantity, while adequate to produce the best effects of this valuable uric acid solvent on the organism, is strictly limited to such a dose as cannot possibly cause any cardiac debility, or increase it where it exists.

They have taken the natural mineral water of the **Johannis** Springs—containing as it does, in admirable proportions, Sodium Bicarbonate, small quantities of Sodium Chloride, as well as other valuable constituents, impregnated also, as it is, with its own absolutely natural and pure Carbonic Acid Gas—and to this water they have added a definite and constant quantity of Lithium Bicarbonate, so that each bottle shall contain one grain of this Salt of Lithium.

The Medical Profession, by prescribing for those suffering from or apprehensive of uric acid maladies, say, 2 to 5 bottles of Lithiated Johannis water per day, will administer regularly from 2 to 5 grains of Lithium Bicarbonate, combined with the other alkaline constituents of this valuable natural water, and their patients will have the great advantage of drinking a perfectly pure natural mineral water containing just as much of this uric acid solvent as is needed, and no more; while the additional eliminative and purifying properties of the Natural Johannis Water greatly enhance its value for the gouty constitution.

Per Case, 100 Small Glass Bottles

BENGER'S

GOLD MEDAL AWARDED

Health Exhibition, London.

FOR INFANTS, INVALIDS, ROOD.

This delicious highly nutritive and most easily digested Food is specially prepared for Infants, and for those whose digestive powers have been weakened by illness or age.

The following letter addressed to F. B. BENGER & CO., Ltd., is published by special permission of the Russian Court.

"Balmoral Castle.

"Scotland, 25th Sept., 1896.

"Sirs,—Please forward to Balmoral Castle one dozen 2/6 Tins of BENGER'S FOOD for H.I.M. THE EMPRESS OF RUSSIA, addressed to Miss Coster. We have received the box ordered from Peterhoff.

"Yours truly, F. COSTER."

BENGER'S FOOD is sold in Tins at 1/6, 2/6, and 5/-, by Chemists, &c., everywhere.

Wholesale of all Wholesale Houses and Shippers, or of the Manufacturers,

F. B. BENGER & CO., Ltd., Otter Works, Manchester.

TELEGRAPHIC ADDRESS: "Benger's, Manchester."

The Lancet describes it as "Mr. Benger's admirable preparation."

THE MEDICAL PRESS says:—"Few modern improvements in Pharmacy have done so much as Benger's Preparations to assist the Physician in his treatment of the sick."

The British Medical Journal says:—"Benger's Food has by its excellence established a reputation of its own."

The Illustrated Medical News says:—" Infants do remarkably well on it. There is certainly a great future before it."

A Government Medical Officer writes:—"I began using your Food when my son was only a fortnight old, and now (five months) he is as fine a boy as you could wish to see."

From an eminent Surgeon:—"After a lengthened experience of Foods, both at home and in India, I consider Benger's Food incomparably superior to any I have ever prescribed."

A Lady writes:—"Really I consider that, humanly speaking, Benger's Food entirely saved baby's life. I had tried four other well-known Foods, but he could digest nothing until we began the 'Benger.' He is now rosy and fattening rapidly."

ON THE RELATION OF GOUT

RHEUMATOID ARTHRITIS.

OPENING REMARKS TO A DISCUSSION BEFORE THE NORTH-WEST LONDON CLINICAL SOCIETY, FEBRUARY 15TH, 1899.

By WM. EWART, M.D., F.R.C.P.,

Senior Physician to St. George's Hospital and to the Belgrave Hospital for Children; Joint Lecturer on Medicine in the Medical School of St. George's Hospital.

(Concluded from page 209.)

I HAVE endeavoured to show that complete divergence exists between typical gout and typical rheumatoid arthritis, yet formerly they were included under one heading, until at the beginning of the century Heberden and Haygarth established the distinction. No serious effort has been made to revive the alleged identity between them. At the same time the confusion which existed between them until 1806, and the fact that we are now discussing a supposed relationship between them, forcibly suggests that there is, if not in the diseases at least in the appearances which come before us, some sufficiently marked outward resemblance. I believe that this resemblance is limited to what may be termed "borderland" cases, and that it has been magnified by the diagnostic perplexity to which they give rise, and it is this un-certainty bearing upon treatment and prognosis which adds so much importance to the subject under discussion.

Thus, whilst no confusion is possible between the two pure types, the practical point is that our diagnosis is apt, nevertheless, to be sometimes difficult, and the inference is that as they come before us the two diseases are not so purely typical as we read of them in books. We might well put down this difficulty to our want of perception, were it proved that the two diseases were not only dissimilar but antagonistic and mutually exclusive. But I venture to think that no universal antagonism exists. Although their general trend is in opposite directions there is a borderland where they meet and sometimes even blend. And to these associations I shall now even blend.

briefly refer.

The Types in which the Two Affections are Associated.

1. The inherited gouty proclivity which has been traced by Sir A. Garrod in a rather large proportion of the sufferers from rheumatoid arthritis is doubtless one of the reasons which lends to the affection in some cases a gouty complexion—and this we expect to find in the female contingent.

2. A more direct association is brought about particularly in this country as a result of the circumstances of the disease. The inactivity which it entails is but too likely to give scope to the climatic or dietetic agencies which tell upon those most susceptible to

gout, and particularly upon males during middle life.

3. But there is also a third group of those of yet stronger gouty tendency in whom the first event is asthenic gout at a relatively early period in adult life, and in whom a progressive failure of nutrition, or one induced by depressing agencies may at a later period bring about the rheumatoid change.

4. Then there is an important group, which has perhaps more than any other influenced the nomenclature and the pathological theories of rheumatoid arthritis in the direction of rheumatism. Some sufferers present a

record both of gout and of rheumatic fever. In harmony with the age period for the two diseases, we find almost invariably that rheumatic fever is the antecedent event, gout the late sequel. Many of these develop rheumatoid changes, and as applied to them, the term rheumatic gout is specially appropriate. But it must be borne in mind that this is not a constant result.

We are thus furnished with four clinical types which agree in some very broad characteristics, and particularly in the symmetrical distribution of lesions, but which present so much individual variety and gradations that it is impossible to isolate them from each other as strictly

The most distinctly defined are that last mentioned and that in which the production of Heberden's nodules in the digits is the chief and sometimes the only visible change. This type is most commonly seen in women. Its pathology and clinical significance are alike obscure.

The cases of early rheumatism with late gout usually present some unmistakably gouty characters by the

side of the rheumatoid.

The second and the third group are less easily defined, and it is in them that diagnosis is most commonly hesitating.

They may come before us under two varieties, or stages, the dry nodose stage, or the stage of effusion, and these call for different lines of treatment.

ACUTE ATTACKS OF GOUT AND OF RHEUMATOID ARTHRITIS COMPARED.

In both diseases we have to deal with acute attacks and with chronic developments. The acute attacks are, as might be expected, the most distinctive, and least likely to give rise to any confusion. The acute attack of articular gout is characteristic, and I need not dwell upon its details, but merely point out that it is made up of an arthritic, of a nervous, and of a vasomotor local disturbance. Its most acute and painful symptoms seem to be due to the extra-articular changes, and particularly to the implication of the nerves and of the circulation.

The acute attacks of rheumatoid arthritis are much less uniform. They are generally regarded as rheumatic and often mistaken at first for pure rheumatism. But closer observation will enable us, I believe, to distinguish among them two distinct types as well as mixed or transitional forms. One of them more closely resembles acute rheumatism in the important feature that the affection is mainly intra-articular. These are the familiar cases of acute effusion occurring either at the outset—or as exacerbations in the course of the disease. The other form is sui generis, unlike rheumatism in many of its features, and in the fact that there may be little effusion, but that there is, as in gout, obvious extre articular disturbance and pain.

From the point of view of a possible relationship to gout these painful attacks, of the more severe type, deserve our attention. In one respect they differ absolutely from acute gout. Instead of being sharp and short they are apt to last almost indefinitely. generally treated as attacks of acute or subscute rheumatiem. But the more sedulously anti-rheumatic methods are applied so much the worse may the patient's sufferings become, and so much the more lasting the pyrexia. The aching, the pain, and the fixation of the joints are perpetuated instead of relieved by blankets, fomentations and medicines, and the case seems to be interminable.
This peculiar behaviour is diagnostic of this type, and affords the clue to the only successful treatment.

The onset of amendment dates from the moment when

the treatment is reversed, the sufferer allowed to lie in a cooler bed, and cold spongings and rubbings, so ill-borne in acute rheumatism, applied to the joints and to the general surface.

It is significant that in some of these cases the joints present an erythematous aspect closely analogous to, yet not identical with that of the angry patchy flush seen in cases of acute rheumatic arthritis. It is never, in my experience, capable of being mistaken for the shiny, puffy swelling of acute gout; but the question needs to be considered whether it is not more closely allied to the gouty than to the rheumatic erythema, though there is not any ground for supposing that an uratic factor has any share in its production.

In connection with the striking contrast between this form and the acute synovitic or rheumatic cases previously mentioned, there arises also the question whether it is not more apt to attack those who may possess the

gouty rather than the rheumatic tendency.

Closely allied to this variety, which is sometimes monarthritic and more often polyarthritic, are the acutely painful but apyrexial premonitions or early beginnings of local rheumatoid arthritis, so often mistaken at first for neuralgia or myalgia, and not infrequently for a gouty myalgia or neuralgia.

In all these varieties there are unmistakable nervine and vasomotor factors which should be kept in mind in any attempt to elucidate the pathology of rheumatoid

arthritis.

THE CHRONIC FORMS OF ARTICULAR GOUT AND RHEUMATOID ARTHRITIS.

Great as is the variety of the chronic changes in gout, we find a yet greater variety in the chronic rheumatoid joint affections.

Pure tophaceous gout is from the first, and always unmistakable, and any rheumatoid changes that may supervene never disguise the true nature of the affection.

On the other hand, rheumatoid arthritis in its extreme stage is also sufficiently distinctive. It may be said that the further the rheumatoid degeneration advances the greater is the convergence between its various types, until destruction of the cartilage and eburnation of the articular surfaces of the bone furnish us with an almost uniform end-product.

But before this final stage is reached a series of phases are traversed, the exact nature of which may not be obvious. The family history, the clinical antecedents, and the general aspect of the patient, may be highly suggestive of gout, but the joints themselves may present the characters of arthritis deformans. On the other hand, there may have occurred undoubted rheumatoid changes, but with the lapse of time indications may arise justifying a suspicion that the patient has developed gout, and that gouty arthritis may be now associated with the rheumatoid degeneration.

Three types of rheumatoid joints seem to afford room for some hesitation in diagnosis. They all occur at the

gouty period of life.

In one of them there is symmetrical swelling of the joints with effusion. I regard these cases as much more closely allied to rheumatism than to gout, and as belonging to the group which may be termed "rheumatic arthritis deformans.

In the second variety there is symmetrical enlargement and deformity, but although there may be synovial swelling and peri-articular thickening, there is no effusion. Cases of this kind are sometimes regarded and treated as gout, in spite of there being no tophi, because the patients, chiefly males, may present some gouty dyspeptic symptoms and an aspect analogous to that of asthenic gout. They are usually rheumatoid cases, with more or less constitutional tendency to gout, and it is among them that we may look for instances of the "gouty" variety of rheumatoid arthritis.

Lastly, there is the large group, chiefly of women of mature age, in whom there has been, and there is, no obvious gouty arthritis, and in whom the rheumatoid changes may be limited to the development of Heberden's nodules, and to slight and varying thickening of the wrists or other joints, but in whom, besides a strong gouty family history, there may be marked constitu- internal hygiene is more particularly needed by all tional symptoms, such as are observed in chronic gout. sufferers from joint trouble, whether this be gout

In some of them the gouty tendency becomes more and more developed. Others through careful living remain free from articular gout. But many of them present at the same time a peculiar susceptibility to rheumatic influences from soil and climate. This then is a mixed group, and one specially calling for study from the point of view of the relationship between gout and rheumatoid arthritis.

There are other important varieties to which attention might have been called had time permitted: for instance, the painful monarticular rheumatoid affection of the hip, with relatively slight deformity, in which a gouty family history or a gouty tendency in the individual may often be traced; and again, the chronic rheumatoid affections with deformity, less frequently seen now than in the past, are apt to follow in the train of gonorrheal arthritis. Hutchinson has insisted that this is peculiar to those who inherit a gouty bias.

DIAGNOSIS.

The importance of a correct diagnosis will be obvious when we come to the question of treatment and of diet.

If we admit that the joints in arthritis deformans are liable to gouty phases—or that the patients are liable to gouty states, we must be prepared to find considerable difficulty in correctly estimating the position at any given period in the history of the cases.

My previous remarks have indicated that the distinction between pure gout and pure arthritis deformans is not difficult, and I need not enter into the familiar details of the diagnosis. It is in the ill-developed forms that the uncertainty arises; and this may be best overcome by carefully watching the case and noticing the result of the various forms of treatment. The question is generally as to whether, where the rheumatoid changes are plainly marked, a gouty element is also present or not. But sometimes we may have to determine whether the deformity of the joints is not essentially gouty, the nontophaceous variety of gout closely imitating the distri-bution and aspect of rheumatoid arthritis. For practical purposes the diagnosis of these cases lies on the surface. The symmetrical implication of many joints declares the rheumatoid characteristic of inherent delicacy and of vulnerability of articula-tions, whilst the history and the general features and aspect of the patient may be so strongly gouty as to make it evident that the exciting cause of the arthritic changes must have been of a truly gouty nature. Cases of this kind present to us that association which exists more frequently than is commonly supposed, and in which a gouty lesion may have been the starting point of a rheumatoid arthritic change, or in which an early rheumatoid arthritis may have been fed up into gout. Had the case been straightforward, with creaking joints and a velvety moist palm, as in rheumatoid arthritis, no doubt would exist; but the palm may be as dry as that of gout, and the creakings may not be obtainable. In such a case there is doubtless much of gout in spite of the evidence of arthritis deformans. It is reasonable to infer that the one condition has supervened upon the other, and, therefore, our diagnosis must take into account, besides the permanent changes of arthritis deformans, the fluctuating phases of gout.

TREATMENT AND DIET.

We need not enter fully into a description of the treatment of gout and rheumatoid arthritis, but only so far as it bears upon the relationship between the two diseases.

In the first place, it may be stated that the treatment which is most beneficial in pure gout is that which is most detrimental for the worst cases of that form which we may term "pure" rheumatoid arthritis, to which colchicum and alkalies would be almost poison, and low living the sure means of aggravation.

The relation between the two forms of treatment is thus one of direct opposition as regards their specialisations. Yet there is a considerable basis common to both. Hygiene is essential to all classes of sufferers, but specially to those afflicted with chronic ailments; and

rheumatism, or rheumatoid arthritis—in addition to the essentials of a wholesome dietary.

Our difficulties begin with the management of the mixed forms. Where the indications are not absolutely clear our action is of necessity somewhat tentative. In most of the cases to which reference has been made there is, besides the rheumatoid basis, a suspicion of the gouty element. I believe that in many of these cases the best treatment is to treat the rheumatoid arthritis as thoroughly as this may be wisely done, and to be sparing with the more energetic remedies for gout. Our most important duty seems to be not to add in the slightest way to the depressing conditions under which the rheumatoid patient is suffering. A relatively lesser evil would be to temporarily increase his gout. But even this need not occur if our treatment be happily conceived.

There is one direction in which the treatment of both affections can be carried out with safety and benefit almost irrespective of their special characters. I refer to the local measures of relief to the joint. We are now provided with additional means and most effectual ones of local treatment. It had long been noticed that the old-fashioned balnear treatment, which is often most serviceable in gout, led to very imperfect and often detrimental results in rheumatoid arthritis, I mean the treatment of the patient by prolonged immersion in a hot bath. The same debilitating effect would result in some of the mixed varieties of rheumatoid arthritis in spite of their gouty complication. The general balnear treatment had of late years been abandoned in all such cases for the more local measures of steaming, hot douching and massage applied more especially to the joints affected, and our chief success had hitherto been derived from this method. We are now provided with various means of treating the joint affected by dry heat up to very high temperatures. The careful application of these new methods graduated to each case will enable us to feel that a great deal is done for the joint, whilst no possible harm is suffered by the patient whichever be the stage of his articular complaint.

Dr. Levison in a most interesting article has provided us with suggestions as to the diagnosis between rheumatoid arthritis and gout by the X-Rays, and as to the treatment of the gouty joint by the electrolytic method. Thus electricity, which had long been known to be of considerable use, whether in the shape of the electric bath or of the constant current directly applied to the limb in cases of rheumatoid arthritis has now found a yet more direct application in gout since it addresses itself to the removal of the material which is the source of local irritation and pain.

Meanwhile the internal treatment of such cases may be carried out on lines conformable not only to some of the obvious indications, but also to theories which are in some respects divergent. The abundant use of water as the means of accelerating excretion of waste products and of all forms of toxins, and assiduous attention to the activity of the bowels are equally desirable in gout and in rheumatoid arthritis, and fulfil the indications claimed by the neural as well us by the humoral theory.

In mixed cases occurring in mature age it may be best not to complicate the position by any vigorous tonic treatment, nor even by the iodide of iron which has found so much favour since first advocated by Sir A. Garrod, and which is admirably suited to the uncomplicated form witnessed in children and young adults. There may, nevertheless, be room for the administration of arsenic in small doses and of sulphur, in addition to the purgatives. These have also been largely prescribed by the same authority before the more recent ideas concerning the septic origin of rheumatoid arthritis had been set forth. It may be said for a senic that in addition to its antiseptic properties it must approve itself to those who regard arthritis deformans as conditioned largely by a disordered nervous function.

Those are some of the general lines upon which doubtful cases may be treated safely, and with the promise of much benefit.

Reference has been made to the acute and painful forms of rheumatoid arthritis, frequently monarticular,

in which an inherited gouty proclivity or an acquired tendency to gout may be a factor. As previously suggested, treatment comes to the aid of diagnosis in these cases so apt to puzzle us. Anti-rheumatic remedies and methods of treatment are absolutely harmful and there is a positive intolerance—though this is not always thought of by those in charge nor even often realised by the patients themselves-for the ordinary heat of the rheumatic bed. Let this influence be removed and they are immediately benefited. I regard this variety of complaint, long ago described as an affection sui generis and successfully treated by Dr. Fuller, as a special form of successfully treated by Dr. runer, as a special form of rheumatoid arthritis, of a vaso-motor type; and in treating it I am impressed with the necessity of addressing the treatment to the vaso-motor system. The best way to do this is the application of heat or of cold. Whilst we had remained restricted to the former methods of thermal treatment, treatment by heat had often failed, and the application of cold had been found to be the only successful method in some cases, after trying in vain the use of hot spongings or even of the hot-air bath. Now that different methods are available it is conceivable that cases of this kind. although refractory to ordinary heat, may be relieved by the heat cure and derive great advantage from the high temperatures generated by electricity and by other means, as they certainly do from cold applied locally.

As regards the general and medicinal treatment of this variety, it must vary with the individual characteristics of the patient, but in the average case most advantage would be gained by our disregarding indications derived from a mistaken diagnosis of rheumatism, and by our not being deterred by the gouty family history or personal antecedents from endeavouring to raise the general strength of the patient. This practical view would also meet the indications suggested by any toxic theory which might be entertained by some in preference to the neural vasomotor theory.

The antiseptic treatment by the internal administration of creasotes, phenols, and naphthols, recommended by Bannatyne, and the local germicidal intra-articular treatment by means of iodoform, carbolic acid, and other germicides practised by Max Schüller are too important to be passed altogether unnoticed, but they are specially intended for the infective form of the disease, and they have not, so far as we know, a direct bearing upon the subject of our discussion to-night.

Lastly, we come to the questions of diet and of alcohol, the answer to which is foreshadowed in my preceding remarks. The rheumatoid patient needs, above all, to be fed, and wine suits him well; but if he should turn gouty we cannot disregard his gout. It is pre-eminently in this connection that the practical purpose of this discussion is revealed. How to diet the patient and whether or not to allow him alcoholic stimulation are points not to be safely decided except on the strength of an accurate diagnosis not only of the general character of the case, but of its special phase. In doubtful cases there is pro-bably more rheumatoid arthritis about the patient than gout, and I am in favour of the policy, which I have indicated in my remarks on treatment, of running the risk of a slight gouty exacerbation rather than of incur-ring the reproach of intensifying the depression and debility inseparable from the rheumatoid state. The gouty element, if present, may, however, restrict the choice of stimulants to those more suited to gout; whereas in uncomplicated rheumatoid arthritis, particularly that of the young, the prevailing anemia calls for a supply of the red wines. In both cases the delicacy of the digestion has always to be borne in mind, and it is equally essential that the diet should be easily digestible, and that it should be sufficiently varied and nutritions

THE death occurred at Southsea, last week, after a long illness, of Lieutenant-Colonel P. R. Gabbett, Royal Army Medical Corps. He had served in the Army at home and abroad for twenty-eight years, and was recently principal medical officer in Barbadog.

GYNÆCOLOGY IN RELATION TO SURGERY. (a)

By ALBAN DORAN, F.R.C.S.,

President of the Obstetrical Society; Surgeon to the Samaritan Free Hospital, &c.

AFTER remarking on the curious circumstance that although he was the twenty-first President of the Society, he was the first surgeon and the first President holding no University degree, Mr. Doran compared the state of affairs in obstetrics and gynæcology in 1859, as gleaned from the Transactions of that and succeeding years, and contrasted them with the present position of things in these two departments. He pointed out that the growth of obstetric pathology had been comparatively slow, but under the stimulating influence of the Society had of late years made distinct and encouraging progress.

He then proceeded to discuss gynæcological surgery, its triumphs and its abuses, pointing with pride to the fact that general surgery was more indebted to it than it was indebted to general surgery. He cautioned them, however, that just as law was not always identical with justice, so operating by no means necessarily meant surgery. Ovariotomy, however, had undoubtedly revolutionised abdominal surgery, opening up, as it did, unknown fields, alike to

the general surgeon and to the obstetrician.

Touching on plastic surgery, he referred to the papers of Fleming and Marshall Hall, who, early in the present reign, brought forward their new method of performing anterior-colpotomy, and insisted on their indebtedness to Marion Sims, who, in 1859, was already famous for his skill in the repair of vesicovaginal fistula. This operation had since been much simplified, and there had been great advance in surgical procedures of this class. The removal of the uterus through the vagina, he said, came under the head of surgical novelties. He, however, declined to endorse the gloomy view recently expressed by Dr. Halliday Croom in respect of this operation for cancer. His own experience led him to believe that if it did not cure, it greatly relieved the patient's sufferings and ameliorated the local condition.

Passing on to the history of ovariotomy he pointed out that the operation had afforded surgeons invaluable experience in the cleansing of the peritoneum, its effective drainage, and the flushing of the peritoneal cavity, for which they were originally indebted to Mr. Lawson Tait, though, since its introduction, its utility has been found even greater than he ever suspected it to be in that it acted like a transfusion as well as serving as a hæmostatic, a remover of obnoxious fluids and solids, and a counteractor of shock. He claimed in this connection that the Society had played a conspicuous part in solving

the transfusion question.

Operations for diseases of appendages due to inflammation, he said, might be decidedly bad surgery, or else questionable surgery, or else very good surgery. He pointed out that inflammation of the parametritic or cellulitic type usually subsided under appropriate medication, and he condemned undue hurry in the matter of surgical interference in ordinary puerperal cellulitis. Even old neglected cases with sinuses hardly called for special operative treatment. He had found that puerperal and gonorrhead disease of the appendages might disappear almost spontaneously, and he regretted to read opinions implying that they could not do so. A tender movable ovary should never be removed forthwith, and a tender but recent fixed mass in the pelvis should never be opened or exposed by the kuife until after the effects of medical treatment had been carefully watched. The

case was quite otherwise when inflammatory disease was chronic, with a trustworthy history, in which exploratory incision was often needed. He pointed out that removal of the appendages was often unnecessary, it often sufficing to free them from old adhesions, and he deprecated the view that an operation was imperfect if nothing were taken away. He characterised as vicious the idea that when the appendages were removed on one side they must be removed on the other, insisting on the propriety of minimising operative mutilation as much as possible

The relative merits of vaginal and abdominal operation in the treatment of bad cases of bilateral pyosalpinx was, he observed, still being discussed. The great enemy of success in these cases was the stump which was so often unhealthy and so liable to serve as a source of infection. The removal of the uterus with the suppurating appendages was, he thought, a grave and not absolutely justifiable operation. It was the duty of the surgeon to make sure that his patient did not merely recover from the operation. Commenting on Landau's series of vaginal celiotomies, he pointed out that this observer's tables contained over twenty cases in which the operation had been performed within eight months of their publication, eight within six weeks, and the majority of the operations were for salpingitis or cöphoritis. Another foreign operator registered 424 cures out of 453 extirpations of the uterus and appendages through the vagina, and 95 cures out of 98 extirpations through an abdominal incision-all for suppuration. As the result of this large experience, this operator gave it as his opinion that the risk of operating was not greater by one way than the other. He would have liked this author's definition of the word to know "cure." Out of a total of 519 recoveries what a valuable series of two years' histories they might one day hope to have! He asked incidentally what could have been the cause of such widespread pelvic inflammation that one operator, in a comparatively small town, found it necessary to remove the uterus and appendages in over 500 cases for the cure of that disease, while in London, where all the immediate and predisposing causes of inflammatory disease of the tube and ovary were present, few, if any, of them found it often necessary to proceed to such an extreme measure.

Removal of the ovaries for neurosis was, he thought. unjustifiable, and he referred with satisfaction to the attitude of Dr. Howard Kelly, who, in his standard work, calls attention to the fact that in a recent series of 500 abdominal sections at the Johns Hopkins Hospital only four cases were operated upon for this reason, and admitted that in three of these the relief was not what was looked for. Dr. Weir Mitchell also condemned the removal of sound appendages in the treatment of neuroses. The principle of hysterectomy for fibroids was, he said, agreed upon, though the limits of the operation were still matter for discussion. Admitting that the tumour might not destroy life which the operation might sacrifice, he pointed out that were things quite as precious to patients as life and the operation might involve more risk if delayed until the sufferer had passed through two or three more years of misery or constant discomfort. He suggested that their maxim should be, when in doubt, watch. That had been his practice, but he admitted that some of the cases had been the worse for waiting. He himself would operate on cases of uterine fibroids in patients above forty, when there was steady growth, with softening of the tumour. He thought they ought not to attach too much importance to the supposed risk of the malignant degeneration of fibroids which, judging from statistics, was an extremely rare occurrence. On the other hand he did not

⁽a) Abstract of the Inaugural Address delivered at the Obstetrical Society on March 1st, 1899.

think a fibroid should be removed merely because it "worried" a patient. Such a patient should be told that fibroid was not cancer, and that while ovarian tumours are always dangerous to life uterine fibroids seldom killed, and were rarely so bad as not to allow of watching. Speculative operating on uterine fibroids must, he thought, be condemned

entirely

Mr. Doran then proceeded to discuss the surgical aspects of uterine displacements in respect of which he thought there was much operative abuse. He admitted, however, that the subject was very complicated, and one could not soundly judge operations without first knowing the pathology of flexions and versions, which was by no means settled. The multiplicity of operative procedures signified that the disease was obstinate, and dependent on conditions not always easy to counteract. To judge of the value of these operations, long after-histories were indispensable, a point which many foreign writers ignored.

In conclusion, Mr. Doran observed that gynæcological surgery had undoubtedly done great service, though, as in every other branch of surgery, while much was good and well-established, much remained uncertain. He urged that they should not be too eager to blame others who appeared to do too much, or who left undone that which it seemed they ought to have done. Surgical procedures, he observed, were only justified when clinical research had proved that there was something which ought to be removed or rectified. Patient clinical research was, in fact, the sheet anchor of the gynæcological surgeon.

A NOTE ON THE

TREATMENT OF TUBERCULOSIS

FALKENSTEIN.

By E. MACDOWEL COSGRAVE, M.D.Dub., F.R.C.P.I.,

Professor of Biology, R.C.S.I., Physician to Cork Street Hospital, Dublin.

THE Prince of Wales's mention of his visit to Falkenstein at the meeting held in Marlborough House in connection with the National Association for the Prevention of Consumption, and the probability that the institution so well organised by Dr. Dettweiler will be adopted as a model for the Sanatoria shortly to be erected in the British Isles, may render of present interest a short note on the details of the treatment there carried out.

Falkenstein is a comparatively new health station, having been founded in 1874, and has still more recently become known to the English. Bradshaw, in 1898 Ed. of "Bathing Places and Climatic Health Resorts," only devotes six lines to it, whilst

St. Moritz gets three pages.

The Sanatorium is worked by a company, who, however, cannot receive more than five per cent. interest, any surplus going to extend the establishment, or to afford similiar advantages to poor

The Sanatorium is situated at a height of 1,300 ft. on the southern slope of the Taunus mountains, it faces the south east where the ground falls some thousand feet to the valley of the Maine, and to Frankfort, and is protected on the three other sides by the higher portions of the Taunus range. The climate is cold in winter, but although there are fogs the atmosphere is singularly free from winds and dust, and there is no perceptible fall of temperature at sunset.

The main building is in plan like a wide horseshoe,

and encloses a gravel terrace, along which extend covered verandahs. In these cane sofas or deck-chairs are ranged, and on these the patients spend practically the entire day.

Additional pavilions are placed in the grounds, some of these revolve so that they may be turned to avoid the wind and catch the sun; the Germans have with somewhat grim humour christened the pavilions by such names as "The Hall of Sighs," "The Temple

of Bacilli.'

For the first few days the patients only lie out from after the second breakfast to 5 p.m., but afterwards the day's routine is as follows:-After ten minutes' rubbing by an attendant the patients assemble at early breakfast, which in summer is from 7 to 8, and in winter from 7.30 to 8.30; this consists of coffee, rolls and butter, and, in addition, hot or cold milk ad lib., the watchful attendant at once replenishing empty glasses.

Then the balcony is sought, and the patients lie down, placing their feet in fur bags, and wrapping rugs and shawls about them. The wraps belong to the patients, and must be provided as part of their

outfit.

The expertest of packers then goes round and rapidly and skilfully tucks in the patients, who then appear like symmetrical and well-cared mummies.

At 10 o'clock they go in for second breakfast, which consists of rolls and butter, and hot or cold milk ad lib.; to those who, in the opinion of the medical attendant need it, strengthening soup is served.

They again lie on the verandah until they go in for dinner at 1 p.m. This and supper are of the kind usually served in German hotels, but special attention is paid to making each course as nourishing as possible, and each meal commences with one of the thick nourishing soups that form a Falkenstein specialty.

At 4 p.m. milk is brought round the verandah, this, as well as the 9 p.m. milk, is not included in the regular tariff, but is served at a cost of one

penny per glass.

All the milk used at the Sanatorium comes from the dairy of the establishment which is situated on a hill-side up above, and is sterilised. For those who cannot digest so much milk koumiss is provided.

The patients are encouraged to drink plenty of

milk and generally take from six to eight tumblers a day, which is a large amount for people who are taking daily four solid meals. Occasionally the amount of milk has to be limited, as lately happened to a home-sick American who tried to expedite his cure by drinking fifteen glasses a day. Supper is at 7 p.m., and after it the patients may lie out to 9 or 9.30 p.m., at 9 p.m. milk is served round. The patients then retire to their bedrooms, which are warmed by pipes; the windows, however, are left open during the night.

When the patients arrive they are thoroughly overhauled by the entire medical staff; this is repeated monthly, a daily inspection being made by one of the resident medical men. Their temperatures are taken four times daily-at rising, noon, 4 p.m., night—if the temperature shows fluctuation it is taken eight times daily. It is interesting to see how when the clock strikes twelve and four all the recumbent patients pull out their thermometers and place them in their mouths until they are ready to be entered on the charts. These hours are anxious ones to those with a temperature tending to run above normal, as the penalty for raised temperature is banishment to the bedroom until it again becomes

The sanitation of Falkenstein is excellent, there is an abundant water supply from pure springs situated higher up the mountains, and the sewage is received in precipitation tanks. The whole place is kept

scrupulously clean, and constant war is waged on dust.

Although the Sanatorium is surrounded by extensive woods with tempting walks, they are out of bounds for the majority of patients, who are required to rest as much as possible: indeed, even needlework is practically prohibited, and letter-writing is discouraged. It is only when patients are nearly well and about to leave that they are allowed to take walking exercise, and even then the distances allowed are short, and the limits fixed are strictly observed.

It will be seen from the above that rest, air, and food are the three means of cure, and that these are administered with no stinting hand, Complete physical idleness, twelve hours in the open air, the night spent in a room with open windows, and frequent full meals of nutritious foods, with plenty of milk in between, take the place of medicines; it is wonderful how the treatment agrees with the patients, and how the long exposure to the fresh air does not cause cold, and how the frequent meals are awaited with sharp-set appetite. Of the benefit of the treatment in the majority of cases there can be no doubt, and that not only in incipient cases, but even when both lungs are affected.

Falkenstein is easily reached; the Great Eastern Railway offers the best route by Harwich and the Hook of Holland, the journey can be conveniently broken at Cologne, which is reached in the middle of the day, and can be finished by another half-day's travelling, train being taken to Frankfort and on a few miles to Cronberg, where carriages meet expected

guests.

Whether equally good stations can be found in the British Isles is at present an urgent question, as although Falkenstein is easily reached, treatment abroad means greater separation and isolation than treatment at home. It is probable, however, that our insular climate will not give as equable winter temperature as can be met with on the European continent, and that whilst Sanatoria at home may do for early cases, those that are more advanced will have to seek the Continent, so that even if English Sanatoria are opened Falkenstein will still draw its quota of English cases.

A SERIES OF CASES POINTING TO THE

IDENTITY OF THE CAUSE OF ACUTE RHEUMATISM—CHOREA—ENDOCARDITIS AND ERYTHEMA NODOSUM.

By F. DEAS, M.R.C.S., L.R.C.P., Late House Surgeon, Liverpool Stanley Hospital.

During two years' residence in the Liverpool Stanley Hospital I had many opportunities of studying cases of acute rheumatism and kindred affections, and of making exhaustive inquiries into the family histories of such cases.

I think the following cases present features of sufficient interest or rarity to warrant their publication, and point to an identity of cause in the diseases named above. In offering them for record I must express my best thanks to Dis. Whitford and Macalister for their permission to use my notes on cases

which came under their care at the Stanley Hospital. Case I.—M. D——, female, et. 13. This patient had been quite well up to the day before admission. She then complained of pains all over, headache, sore throat, and sickness. Immediately after admission she had a rigor, and her temperature rose to 104 degs. Fahr. She then complained of acute pain in both elbows and wrists. These joints were swollen, hot, and tender. She was sweating profusely—the peculiar sour sweat of acute rheumatism.

At the same time there were present the typical inco-ordinate voluntary movements, and irregular involuntary movements of chorea affecting the same limbs. Heart and lungs were normal. The patient was put on salicylate treatment, and at the end of the eighth day the temperature had become normal. The choreic movements continued, with gradually decreasing intensity, until the same day, when they entirely ceased. On the third day a small patch of pleurisy was found at the right apex, and a fortnight later a soft systolic bruit was heard at the cardiac apex. All the affections had disappeared by the eighth day. There was a history of acute rheumatism on the mother's side.

Case II.—Ellen T., æt. 12. This patient was admitted for acute chorea. The movements were so violent and incessant that she had to be fed under an anæsthetic. Two days after admission a punctiform erythematous rash, like scarlet fever, appeared all over the trunk, and on the front of both legs several typical patches of erythema nodosum. No drugs had any effect on the disease, and the patient died on the fourth day. No post-mortem examination was allowed. There was a strong rheumatic history on the side of the mother, and one less definite on the

father's side.

Cases III., IV., and V.—These were three sisters attending the out-patient department. Jane M., æt. 17, Annie and Ellen M. (twins), æt. 15. The eldest girl was under treatment for slight dyspnæa and ædema, due to double mitral disease. She had never had any other rheumatic manifestation. Of the twins, Annie had chorea and no heart affection. Ellen had had acute rheumatism a year before I saw her. and was attending for double mitral disease. Both parents had suffered from rheumatic fever before marriage, and both had a systolic bruit.

The conclusions to be drawn from these cases. I think, point strongly to the presumption that the materies morbi was originally the same in each case. The simultaneous occurrence of rheumatic fever and chorea is, I believe, unique. In Case II. there were again two distinct manifestations present at the same time. In Cases III., IV., and V. separate and distinct manifestations appeared in three members of the same family, different tissues being selected in two

members who were twins.

In all the cases hereditary tendency was definite, and in the last three cases double inheritance was well marked. I think one is justified in concluding that in each case the primary cause was the same; its different manifestations being due to different tissue selection, or to a modification of the same materies morbi. The last three cases are rendered more striking, and perhaps conclusive, by the fact that hereditary tendency was extremely well marked in the family. All three girls had been the subject of "atresia vaginæ." The mother, her two sisters, and the maternal grandmother had all been affected in the same way, requiring a little surgical interference at puberty.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.
MEETING HELD WEDNESDAY, MARCH 2ND, 1899.

The President, Mr. Alban Doran, in the Chair.

Dr. W. J. Smyly (Dublin) showed three myomatous uteri which he had removed per vaginam by Doyen's method. The indication for operation in all the cases had been hæmorrhage. The first specimen had heen removed from an unmarried woman, at. 42, from whom a pedunculated myoma had been removed six years previously with temporary benefit. When admitted to

hospital in September, 1898, she was in a condition of profound anæmia. The uterus was again explored, but nothing removable discovered. After some weeks spent in endeavouring to improve her condition the uterus was extirpated November 14th. Convalescence satisfactory. The second case was operated upon on January 14th, 1899. The patient was a married woman who had borne two children. Convalescence was delayed by phlebitis of the right saphenous vein. The third patient was also a married woman who had borne children; the operation, which was a very easy one, occupying twentyoperation, which was a very easy one, occupying twenty-three minutes, was performed on February 2nd, 1899. She made a rapid recovery. Adding these three cases to seventeen which he had reported at the Edinburgh meeting of the British Medical Association, made twenty cases operated upon by this method, with one death, a mortality of 5 per cent. He said the shock was less, the mortality smaller, and convalescence more rapid after vaginal than after abdominal hysterectomy. There was no abdominal wound which might develop a hernia, and he believed that intestinal adhesions and ileus were more rare. He did not believe that in any of his cases the tumours could have been removed without sacrificing the

A SECOND CASE OF PRIMARY CARCINOMA OF THE FALLOPIAN TUBE.

Dr. C. HUBERT ROBERTS related the case of a woman. et. 60, married, but never pregnant, previously well, who in June, 1897, had a sudden discharge of cherry-coloured watery fluid, lasting three days. The menopause had supervened ten years before. In July she was examined by the vagina and abdomen, but nothing was discovered. Iron and ergot were prescribed, and the discharge ceased. Nothing further happened till September, 1897, when a fairly profuse discharge again occurred. During the preceding months two or three further vaginal and abdominal examinations were made, but nothing definite was discovered. In April, 1898, examination revealed the presence of a swelling to the left of and behind the uterus, which it was thought might be an ovarian cyst. Later in that month Mr. Meredith saw the case and advised an exploratory operation, the swelling in the meantime having increased in size. The uterus was quite small and senile in character. On May 5th, 1898, the abdomen was opened in the usual manner, and with considerable difficulty a large tumour was raised from the left of Douglas's pouch which looked like a distended Fallopian tube. Beneath it a cystic ovary could be seen. At this stage the tube ruptured and a handful of putty-like material escaped. It was evidently a distended and diseased tube, but the uterine end appeared to be comparatively healthy. It was removed along with the ovary. The other tube and ovary being small and apparently healthy were left. There was no free fluid in the peritoneum which was flushed out, and the wound closed without drainage. In November, 1898, there had been no return of the discharge and the discomfort. In January, 1899, a subsequent report was received of a less satisfactory character and no doubt remained that recurrence had taken place, e.g., within eight months of the operation. The specimen consisted of a much enlarged and sacculated Fallopian tube, which contained only a small amount of fluid. On opening up the remainder it was seen to be dising up the remainder it was seen to be dis-tended by a villous or papillomatous growth which appeared to spring from the walls of the tube. Sections thereof showed it to be carcinomatous. The author pointed out that cases of papilloma and carcinoma of the tube are very rare, though this was the accord appearance of the kind which he had been was the second specimen of the kind which he had been enabled to bring before the society. It closely resembled his other specimen. The growth had formed in a normally constituted tube. He thought the growth might have begun as a papilloma, though it had undoubtedly become carcinomatous. He remarked that free fluid in the peritoneum was always a suspicious circumstance, but in this case it was absent. He added that he had never heard of a case of primary carcinoma of the tube under the age of 36.

mencement of this case, he took it that there was very strong reason to suspect that it was originally a papilloma which had undergone carcinomatous degeneration, but he did not think the question could be quite settled until they met a case rather earlier in its course. With a case as advanced as this one, he did not think it would be safe to do more than hazard a conjecture as to the mode in which the carcinoma had originated. Although he himself had seen a good many cases of tubal disease, he had never come across an instance of this disease. He imagined consequently that it must be an exceedingly rare disease, only less rare than carcinoma of the tube itself.

Dr. Inglis Parsons asked whether pain was a prominent symptom in the earlier stages?

Dr. ROBERTS said the first symptom was discharge. but in the second attack the pain preceded the discharge as if the tube were distended and had been relieved by the flow.

Dr. A. Routh observed that one of the important points in this case was the difficulty of diagnosis. In the first case mentioned in the tables-a case brought forward by the President and himself, the diagnosis was made after dilating the uterus. The patient had at first no tumour on either side of the uterus, though she had this watery blood-stained discharge. This was at first attributed to senile endometritis, and the uterus was dilated, but nothing was found. Within a week or two she had some sort of pelvic inflammatory attack, and when that cleared away the tube was distinctly felt and was subsequently removed. With regard to papilloma becoming malignant, his impression was that when it did so it remained a recognisable papilloma microscopically. In a case of papillomatous uterus after curetting several times. he determined to remove the uterus the next time it recurred. He did so, and then it was found that the papilloma had penetrated the walls of the uterus to just beneath the peritoneum, presenting appearances not at all like the sections that had been shown them.

The PRESIDENT said they hardly knew whether papilloma was a neoplasm or an inflammatory product. Dolery had written a very good paper on the subject, showing that it was akin to mucous warts, i.e., that it was a purely inflammatory product which might become malignant. He thought cancer only began in an unhealthy tube. Last Thursday he had come across a case in an old woman. It had gone on so quietly that they thought it was a case of old fibroid of the uterus which, after quiesence, was becoming cystic. It proved to be a very large and very ugly malignant papilloms of the tube, which was filled with the growth. After enucleation there remained a large mass in Douglas's pouch, and there was a bud of the growth in the uterus. She died twenty-seven hours later, and post-mortem she was found to be perfectly riddled with cancer. The papilloma did not look so very malignant in the tube, and he was not sure that it might not have been inflammatory. One thing was certain, viz., that, however caused, cancer of the tube was very malignant. He urged that the attention of surgical registrars and pathologists should be directed to the subject to induce them to look for every trace of cancerous disease commencing in the tubes.

Dr. ROBERTS, in reply, said the chief symptom that might lead them to diagnose a case of this kind was, a number of years after the menopause, the appearance of this characteristic watery discharge.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF MEDICINE.

MRETING HELD JANUARY 27th, 1899.

The President, Dr. JOHN W. MOORE, in the Chair.

A CASE OF ERB'S JUVENILE FORM OF MUSCULAR ATROPHY.

DR. LANGFORD SYMES exhibited a case of juvenile Dr. Cullingworth said that with regard to the com- muscular atrophy. The patient was a boy, set. 81. He

was brought for advice for his "inability to walk properly," and has been ailing since he was two years old. It began when he was learning to walk. If he fell he could not get up alone; he is now getting more helpless, cannot walk upstairs, and is unable to get in or out of bed.

Dr. J. B. COLEMAN.—(a) A Case of Progressive Muscular Atrophy; (b) A Case of Anterior Cornual Myelitis.

THE CLINICAL FEATURES OF BERI BERI.

Dr. CONOLLY NORMAN read a paper on the clinical features of beri-beri. He briefly referred to the uncertainty which still exists with regard to the pathology of the disease, to the difficulties which may occur in diagnosis, and to the unfamiliarity with its symptoms existing among European practitioners until recently. He pointed out that tachycardia is an invariable condition, with extreme irritability of the pulse. Unconform ability of heart and pulse is frequent and striking. Variable murmurs most commonly heard in the pulmonary area are not infrequent, also reduplication of the first or second sound. The heart is frethe first or second sound. The heart is frequently dilated, and this dilatation, chiefly affecting the right side, often comes on with singular rapidity. Death from heart involvement is common, sometimes occurring quite suddenly, and in apparent convalescence, sometimes after a prolonged agony. sensory symptoms, always occurring primarily in the lower extremities, and sometimes confined to the legs. consist of various degrees of superficial anæsthesia and hypo-esthesia combined usually with peresthesia and hyperesthesia, (painful anesthesia). Deep (muscular) tenderness and tenderness of the nerve trunks coexist with loss, diminution, or alteration of superficial sensation. Spontaneous pain (aching and cramps in muscles, painful formication in skin) are common. Œdema is probably always present, though sometimes very slight and transitory. It varies in character, being usually less marked than in ordinary anasarca, say from Bright's disease, and sometimes approaching closely to the "solid edema" of the myxedematous state. It may be slight, fugacious, and confined to the prætibial region or it may spread all over the body. Cases which are highly edematous constitute the so-called "wet form" of beriberi. Effusions into the joints are rare, but common in the serous cavities, especially in pleura and pericardium. In the latter situation they often accelerate death, which may also be brought about or hastened by ædema of the lungs. The motor symptoms are paralysis of various muscles or groups of muscles. The muscles first attacked are usually those supplied by the peroneal nerve. The gait in well-marked cases is characteristically neurotic. The greater engagement and less resistance of the extensors gives the shifting equilibrium in standing, the dropped and inverted foot, the high action in walking (de marche du strpper). The paralysis rarely involves the upper extremities. The muscles of respiration not rarely suffer, particularly the diaphragm, a fact which constitutes one of the dangers of the disease. The muscles engaged tend to waste rapidly. When this wasting occurs after œdema has been slight and transient, the "dry "or "atrophic" form of the disease is produced, but the wasting may coincide with extensive anasarca, only becoming manifest when the latter has abated. He pointed out the importance of recognising the affection, which would appear to be spreading. Since 1894, when it first appeared in the Richmond Asylum, epidemics have been reported from two asylums in the United States, a few cases strongly recalling beri-beri have been reported from German asylums, and an epidemic has occurred in the autumn of 1897 in an asylum in the South of France, which attacked 150 patients, of whom about 40 died. Dr. Norman exhibited a number of photographs of beri-beri patients from the Richmond Asylum epidemics, showing also the peculiar dropping and inversion of the feet, and demonstrating the peculiar relaxation of the joints which occurs in this disease. For purposes of comparison, he exhibited some photographs of cases of alcoholic neuritis and tabes dorsalis.

Dr. Smith considered that the diagnosis of beri-beri was easy only when it occurred in places where the disease might be expected, or when one was already familiar with it. Quite lately two Norwegian sailors

who came from Florida, were admitted to Sir Patrick Dun's Hospital. The main symptoms which they presented were a curious combination of motor, sensory, and trophic conditions, which he thought would be hard to fit in with any other diagnosis than that of beri-beri. They would have been labelled probably as either cases of alcoholic neuritis; or perhaps some more high-sounding name, if the disease had not already been known in Dublin. It was a singular fact that on removing patients in the earlier stages of this disease to new surroundings they were likely to recover-a thing that would not happen in the case of other infective diseases. There was no use in removing a typhus fever patient to a place where there were no other cases of the same disease, though such a procedure was of benefit to the beri-beri patient. On account of this fact Dr. Manson supported the theory that it was due to a peculiar poison which was distilled, so to speak, from the soil, the building, and the surroundings in which the patient lived, and by removing them from these surroundings they removed the cause. He thought that the most interesting point in the morbid anatomy and clinical history of the disease was the remarkable and serious interference with the neuromuscular apparatus of the heart. The only other disease offering a pathological parallel to this was diphtheria, for in that disease, like in beri-beri, the heart was often heavily hit, and an interesting comparison might be drawn between the cardiac symptoms of these two diseases.

Dr. LITTLEDALE remarked that the appearance and disappearance of anæsthesia was a curious symptom. In a case he had under observation he discovered anæsthesia and analgesia over the shins and peronei muscles attempting to demonstrate this to a friend on the day after observing it, the patient immediately jumped on being pricked with a pin. On trying the electrical reactions in this patient he found that a current which would cause most violent contraction in his own muscles would have little or no effect on the patient.

Dr. Dawson said he had had the opportunity of examining the phrenic and vagi nerves in a few of the Richmond Asylum cases, and he found these nerves degenerated, showing the ordinary lesions of peripheral neuritis. In some cases the myelin could be seen to be breaking up into globules.

Mr. Croly, Dr. Knott, and Dr. Martley also joined in

the discussion.

Dr. Norman, replying, said that Manson's opinion that the poison of the disease lurked about the soil of buildings seemed to be supported by appearances. Several writers on the subject had pointed out the seeming liability there was to an outbreak of beri-beri where the soil had been recently turned over, and this led them to think that it was a miasmatic disease. Some even had gone so far as to say that it was malaria. In answer to questions, he said that he had not found the spleen or liver enlarged in his cases. He had not noticed any change in the hair or nails. He remembered one case in which the teeth had all fallen out, but he did not think this was due to beri-beri. One patient had exhibited a series of herpetic patches, which turned into bulke, and left little ulcers after them. There were three or four cases ushered in by a curious eruption not distinguishable by him from erythema nodosum. He could not enlighten Mr. Croly as to why beri-beri should occur chiefly in asylums in this climate, and among the epileptics in those institutions. He was disappointed in the use of electricity in this affection, more so, since some writers on this subject have said that it was possible to diagnose beri beri before other symptoms occur. found changes of any consequence in the spinal cord, which was disappointing, as other observers have stated that the cells in the anterior cornua were frequently found to be degenerated.

The Section then adjourned.

Dr. Sherrington, F.R.S., Holt Professor of Physiology, University College, Liverpool, has received the Marshall Hall Prize, awarded by the Royal Medical and Chirurgical Society, for his researches.

HARVEIAN SOCIETY OF LONDON. MEETING HELD THURSDAY, FEBRUARY 15TH, 1899.

Mr. HENRY JULEE, F.R.C.S. President, in the Chair.

Dr. ARTHUR WHITFIELD read a paper on VARIETIES OF ECZEMA AND THEIR TREATMENT.

After pointing out that although eczema was one of the commonest of skin diseases, there was no unanimity on the subject of its sub division, Dr. Whitfield referred to the old classificatione of eczema according to etiology, course, and distribution. All these were unsatisfactory, as they either implied a higher state of knowledge than at present existed, or else did violence to the truth by separating different stages of the same disease. The introduction by Unna of the class of seborrhæic eczemas was then discussed, and the evidence upon which this variety was based was examined. Dr. Whitfield pointed out that some of Unna's grounds for including seborrhoea of the scalp and psoriasis in this class were, in his opinion, insufficient, since the histological characters were little else than those of simple inflammation, whilst the bacteriological evidence was incomplete. He then described the characteristics of the seborrhœic groups of eczemas which remained after separating off pityriasis of the scalp and psoriasis. These were (1) follicular origin, (2) sharply defined margins to the patches, (3) serpiginous spread. After quoting a case of Andrej s to show that this variety could occur on parts devoid of glands and follicles, and was possibly parasitic in origin, Dr. Whitfield referred shortly to some other forms, including eczema folliculorism, eczema, mycoticum, and eczema circum-scriptum. These he considered had better be classed under the general heading of seborrhoic eczema until more was known about the parasites forming them. Passing on to the subject of so-called simple eczema, he said that there were two main opinions about its etiology, one that it was parasitic in origin, and the other that it was a constitutional disorder. He then reviewed the evidence in favour of the relationship between eczema and gout, and concluded that although it appeared that gouty persons were more prone to attacks of eczema than others, there was no evidence to show that eczema was invariably associated with gout, nor were there any distinctive points of diagnosis between an eczema in a gouty subject, and one in an otherwise sound individual. Colombine's researches on the urine in eczema were then referred to as tending to prove that there was not any evidence of a toxemia as a cause of eczema. Dr. Whitfield then summed up his remarks by saying that he thought there were at least two main classes of eczema, in one of which there was no proof of a parasitic origin whereas in the other there was a good deal of presumptive evidence that the disease was infective in nature. He then pointed out that the value of an accurate diagnosis lay in the fact that it was much safer to use strong anti-parasitic remedies from the beginning in the treatment of the seborrhæic form than in the so-called simple variety.

Dr. Galloway remarked that he thought that Dr Whitfield had taken an appropriate opportunity for protesting against the too easily accepted hypothesis of the bacterial origin of eczema, and he especially agreed with Dr. Whitfield in protesting that no special coccus, such as the "morococcus," had been discovered to act as a specific organism. If anyone took the trouble to examine carefully the evidence on which Dr. Unna had based his description of his morococcus as the specific cause of seborrheic eczema, it would readily be seen how slight it was. In the case which Dr. Unna demonstrated before the Hamburg Medical Society, in which he had produced what he called his inoculation vesicle from pure cultures of this "white" coccus, the important clinical fact outstanding was that the lesion so produced was not eczema at all, but something much more closely resembling impetigo. From the time of this demonstra-tion, this coccus had been quoted by Unna and many of his disciples as the specific organism in his large group of "seborrheic eczema." About the same time as Dr. Unna, Prof. Welch, of Johns Hopkins University, pub-

lished his observations on the bacteriology of the skin. He showed that the organism which he called the staphylococcus epidermatis albus was a constant denizen in the skin, where it lived a saprophytic existence, and appeared to produce no pathogenic effects. No sufficient evidence is on record to prove that the morococcus is not an organism of the same class, and there is much to support the view that it is simply a saprophyte. One could not help coming to the conclusion that if any organism does produce seborrheic eczema, at any rate, it is not the morococcus. Hefeltinclined to look upon eczema as the ordinary inflammatory reaction of the skin to many varieties of irritation. There was little doubt that among these various irritants bacteria exercised considerable influence. The type of eczema which appeared to be of parasitic origin was the seborrhæic variety, but he wished to emphasise the fact that the evidence in favour of this at the present time is almost completely clinical, and has no definite bacteriological support.

Dr. BAZLY THORNE said that he attached more importance to toxic conditions of the blood in relation to eczema than Dr. Whitfield was disposed to accord to them; and that he could not regard as valid the argument that, if the kidneys were sound they must be innocent of mischief, because they might, by habit and regimen, be inhibited from performance of their normal function. He gave as an instance the case of a lady who had, for seven years, suffered from a severe form of eczema palmaris with inflammation of the matrices and deformity of the nails, amounting, in the index fingers, to partial destruction. The total daily ingestion of fluids, consisting of tea, coffee, and claret, barely amounted to seven-eighths of a pint. In three weeks the disease was arrested by the use of an ointment containing ammoniated mercury, of a mixture containing grain doses of potassium iodide, and by the ingestion of two pints of water daily. The cure, which had been maintained up to the present time, was mainly, if not entirely, due, Dr. Thorne felt convinced to the water, which had restored to the kidneys the power of promoting the purity of the blood. He added that he entertained no fear of the local effect of salt water, as in every instance in which patients affected with seborrheic eczema had, under his observation, undergone a course of saline baths, the skin had become sound before the termination of the treatment. That result might possibly be attributed to the diuresis which the baths, in all cases, induced.

Dr. ALFRED EDDOWES said that he found Unna's "bottle" bacillus so frequently in seborrhæic cases, that he was disposed to think with Unna that it probably had a causal relation to the disease. But this was hardly the time to deal with the bacteriology of eczema in detail. He thought the word eczema should mean a condition, not a definite disease, unless the word were qualified with an adjective. It was useful clinically to speak of seborrhœic eczema, impetiginous eczema, tuberculosis,&c. As for treatment there was much that might be said. It was easy to lay down certain definite principles which were always useful. We should keep in mind the physiological state of normal skin. We must dry a wet skin and grease a dry skin Dabbing with spirit and dusting with powder answered the first requirement, and ointments the latter; while pastes occupied the intermediate place and were most valuable. Take, for instance, a bad case of "scald head," eczema of scalp in a child. One thorough dressing with a paste such as Lassar's, frequently left nothing more to be done by doctor or mother for a whole week, and at once made the case greatly better and quite manageable. He was surprised to hear the reader of the paper say that he did not find pastes of great service.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT THE MEDICAL INSTITUTION, LIVER-POOL, FRIDAY, FEBRUARY 17TH, 1899.

The President, Dr. Donald, in the Chair.

The following specimens were shown:—
Dr. WALKER: (1) Dermoid tumour of ovary. (2)
Ovarian cyst. (3) Scrapings from endometrium.

Dr. Briggs: Diffuse benign adeno-myoma of the uterus, occurring in one horn of a bicornuate uterus.

Dr. Gemmell: Uterus removed for early malignant disease, together with microscopic sections.

Dr. Grimsdale: Multiple fibroids of the uterus complicated with pyo-salpinx, removed by abdominal

hysterectomy.

Dr. S. Buckley read notes of two

CASES OF FIBROIDS COMPLICATING PREGNANCY,

in which abdominal section was performed.

Case 1.—A patient, at. 28, pregnant three and a-half months. The fundus uteri was pushed to the left by a firm rounded swelling reaching up to the umbilicus, and very tender to the touch. On opening the abdomen the mass was found to be a soft fibro-myoma springing from the right side of the uterus. It was not pedunculated, and could only be removed by abdominal hysterectomy. As the symptoms were not urgent the abdomen was closed. The patient made a good recovery, and five months later was delivered naturally of a full-term living child.

Case 2.—Patient, at. 28, five and a-half months pregnant. A tumour, the size of a large cocoa-nut, was found to be springing from the left side of the fundus uteri. It was freely movable, very hard and bad, caused severe pain, the result of localised peritonitis. The abdomen was opened, a pedunculated myoma found attached to the left cornu of the uterus and adherent to the omentum. The pedicle was transfixed and ligatured in the ordinary way, and the tumour removed. The patient made an uninterrupted recovery, and is now almost at full term.

Dr. Arnold Lea read the notes of a case of

SARCOMA OF THE OVARY,

occurring in a girl, æt. 13. The tumour, which had attained the size of a seven months' pregnancy, had been noticed for some months, and had grown rapidly. The mass lay somewhat to the left side, was very soft and freely movable. Per rectum the uterus was small and separate from the tumour, and a pedicle could be felt on the left side. There was no ascites. The patient had menstruated normally twice. Abdominal section was performed. The tumour was adherent to the great omentum, which was removed along with it. The right ovary was normal, and was not taken away. The patient made a good recovery from the operation. The tumour was a soft sarcoma, very vascular, and showing numerous hæmorrhages. Microscopic sections showed it to be of the round-celled variety. The prognosis of sarcoma of the ovary in young girls is very bad. Of twenty-six cases recorded as operated upon, seven died as the result of the operation (27 per cent). Recurrence within a short time is very frequent, many cases dying from secondary growth within a few months of the operation.

Dr. W. K. Wall read a paper on the

TREATMENT OF SEVERE ACCIDENTAL HÆMORRHAGE

generally concealed—based upon a personal experience of thirty-eight cases, and he discussed the treatment of this condition. He maintained that rupture of the membranes, as generally advised, was injudicious, owing to the inertia of the uterus generally present in these cases. He upheld the value of the plug and dilator combined as in de Ribe's bag. After summarising the methods of active delivery "per vias naturales" he discussed the value of abdominal section, expressing the opinion that it could only have a very limited field of usefulness. He suggested that after delivery of the child, if the uterus remained inert and did not respond to ordinary stimuli, vaginal hysterectomy might be justifiable, alleging that many of the fatal cases of concealed accidental hemorrhage were brought about by the intractable post-partum hemorrhage so commonly experienced.

The discussion on this paper was adjourned to the next meeting.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, March 5th, 1899.

THE EMPLOYMENT OF SALINE SOLUTIONS.

At the Société de Thérapeutique, Prof. Bolognesi read a paper on the above subject, which was very exhaustive. In referring to the methods employed, he said that artificial serum could be introduced into the organism by four ways, the serous, vascular, subcutaneous, and intestinal

Intra-serous injections were first proposed by Ponfick, who had remarked that the blood effused into the serous membranes was rapidly absorbed. The injections were nearly always made into the peritoneum by means of an incision made above the umbilicus, and penetrating to the linea alba; the needle was pushed in the operation of tapping for ascites. Perforation of the intestine, which many feared, was rare, but the operation was always painful, and followed by distension of the abdomen. As the slightest failure in antiseptic precautions could produce mortal peritonitis, intra-peritoneal transfusion was but little practised.

Intra-vascular injections were first employed by Hueter, Roux (Lausanne), and Kummel. The vessels chosen were the veins of the bend of the elbow, or the internal saphena vein over the ankle, which passing over the bone is more easy to discover in stout people, and whose calibre is larger than any of those at the bend of the elbow, while the introduction of air at such a distant point from the heart presented but little danger. The quantity of liquid injected varied between one to three litres, with an average of two litres, at a temperature of 86 degs. F. The rapidity of the current should not exceed ten minutes per litre.

Venous injections presented certain inconveniences not entirely exempt from danger. Consequently, many practitioners preferred for these reasons the subcutaneous methods. For inexperienced hands the venous injection was a regular operation; the veins were frequently difficult to discover; timid operators were afraid of introducing air into the veins, and in any case septic accidents might be provoked, such as phlebitis. Pozzi published one case of acute ædema of the lungs as a consequence of the operation. Further, the counter indications, cardiac lesions, and weakness of the myocardium in particular, were more frequent. Bosc, of Montpellier, preceded the injection of the serum by drawing off a litre of blood; while Barré invented a rather complicated apparatus to combine these two operations, so that the amount of blood withdrawn was replaced by its exact equivalent of artificial serum, but there was no necessity of being so precise, as the same effect could be produced by ordinary blood letting and the introduction of the serum subcutaneously.

The subcutaneous method was at present the most frequently employed, and answered to every purpose except in urgent cases requiring the intravenous method. The region chosen should be that rich in cellular tissue, such as the axilla, the abdomen, the thigh, or the gluteal region.

The instruments employed to make these injections were numerous, and varied from that of Dumouthiers to the simple funnel, but the simplest for all intents and

purposes was the ordinary aspirator of Potain, possessed by every practitioner.

The only trouble arising from the subcutaneous method was the pain from the introduction of the needle, which, however, was insignificant, and that produced by the distension of the skin; or, again, the formation of an abscess, but this latter could be avoided with a little

Enemata of salt water were known and employed for a very long time, but it was only within the last two years that this method was substituted for the subcutaneous injections. All knew the facility and rapidity of rectal and intestinal absorption for medicated solutions, and no one was astonished at the extreme rapidity by which enematas of salt water were absorbed. Those enematas strengthened the pulse, rendered the urine abundant and suppressed thirst. They were used by Eitz with great success for uramia, and by Boulengier for post-partum hæmorrhage and for intestinal hæmorrhage in typhoid

In affections of the nervous system, Professor Grasset, of Montpellier, advised saline injections in apoplexy with arterial hypotension. They were proposed in contagious affections such as erysipelas, measles, scarlatina, small-pox, while Professor Tommassi, of Palermo, in certain skin diseases derived benefit from them, especially in chronic eczema, and in lichen attended with great His colleague, Barbier, obtained considerable success with the saline injections in infantile cholera, and generally in all the intestinal affections of infants.

Lancereaux published remarkable effects of subcutaneous injections of a saline gelatine solution in cases of aneurysms (gelatine 5j, saline solution 3x.) injected under the skin of the gluteal region, and renewed once or twice a week, ten to twenty injections were generally sufficient to effect a cure.

Among the counter-indications of the treatment by saline solutions, he would mention heart affections, edema of cardiac origin, dropsies, pulmonary congestive lesions, and renal sclerosis

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 4th, 1899. HEROINE.

Dr. Franz Tauszk (Deutsch Med. Zeitung) has given us his experience with heroine, the new substitute for morphia. It was used in sixteen cases, mostly cases of cough. There were eight cases of phthisis, one of bronchial asthma, one of croupous pneumonia, one of pleuritis, and four of bronchitis. The effect was good in all, the irritability ceased in all cases, or in a short time it was much alleviated. It was very rapid in its action In the case of bronchial asthma the severe attacks did not return after a dose of 0.003 gms. (0.046 grains.) As compared with morphia, in one patient who had taken 0.003 grm. of that drug for weeks for relief of her cough without relieving the distressing night attacks, 0.003 grm. of heroine at once gave relief. In another patient who had taken 0.10 grm. of codeina per diem without relief, 0.003 grm. of heroine acted immediately. In another case, one of phthisis, on whom the round of narcotic sedatives have been tried without benefit, the results of heroine were striking. Patients seemed to

grow accustomed to the medicine, but the result could always be obtained by increasing the dose.

Volkmann's Sammlung contains a paper by Hans Kehr on

THE RESULTS OF 360 OPERATIONS FOR GALL-STONES WITH SPECIAL REFERENCE TO 151 PERFORMED DURING THE PAST TWO YEARS.

The operations of the writer comprise all or nearly all that can be imagined in connection with gall-stones. The mortality of the operation in simple uncomplicated cases was 3.8 per cent. The writer advises early operation before the gall-stones can have been forced into the deeper bile passages. In the earlier periods the operation is less dangerous and also less difficult than when the choledochus has to be opened. When symptoms of obstruction of the passages are present, he proceeds to operate unless evidence is present of the re-establishment of permeability of the duct. Cure of the cholelithiasis by internal remedies the author looks upon as one of the rarest of events. Development of carcinoma he considers one of the dangers to be feared in cases of long continued irritation from gall-stones. The normal procedure is cholecystectomy, and although with this recurrence is possible, he has never seen it. Cholecystectomy is a more radical operation, but it is also more difficult and more dangerous. Ideal cholecystectomy can only be exceptionally performed, a free drainage of the gall-bladder is the surest means of overcoming the catarrh that so often exists.

Dr. Bruch (Budapesth) (D. Med. Z.) has lately made a study of the relation that exists between

BACTERIA AND CHILL.

He concludes that air, water, and soil, i.e., cold air (draughts), cold water, and damp soil may act injuriously through the pathogenic bacteria they contain. These latter, so long as a physiological condition prevails, give no sign of their presence. In a latent or feebly virulent form they produce no effect on the normally healthy individual, but when an irritation is set up (in consequence of great change of temperature, for instance) that acts upon them and threatens to destroy them, they become virulent, and act injuriously on the organism already pathologically predisposed by a chill. Having given his views, he leaves it to a future collective investigation committee of clinicists, pathologists, and bacteriologists to unravel the remainder of the secret connection between these two factors.

At the Medical Society, Hr. Piorkowski showed a SIMPLE PROCESS FOR THE PERFECT DIAGNOSIS OF TYPHOID FEVER.

Two years ago he introduced a method of differentiating between bacterium coli and the typhoid bacillus, and since then he had been engaged in bringing to completion a more perfect process.

Starting from an observation of Hauser, of Erlangen, he suspected that with a small amount of gelatine in the nutrient soil, the growth of the firm offshoots of typhoid bacilli colonies would, perhaps, become even, more distinct. He found that a strongly alkaline reaction for the differentiation of the soil was an advantage. With five per cent. of gelatine the branching out of the colonies was greater, but this became still more characteristic when the concentration was only three per cent. Finally, he decided that the nutrient soil should be prepared as follows:—Two days old normal urine, of sp. gr. of 1020 made alkaline is mixed with

† per cent. of gelatine, filtered without being warmed and placed in a reagent glass. After being stoppered with cotton wool it is sterilised in steam at a temperature of 110 C. This process can only be repeated on the following day, otherwise the mixture is damaged as a nutrient. The typhoid colonies can then be seen to appear in fibre form, proceeding in a peculiar arrangement from a central point in long tendrils, and thus quite different, from the yellow round coli bacilli. The plates are always kept at a temperature of 22 C. (72F.)

The speaker then described his experiments with typhoid stools. Here the typical form appeared in every case. The identity of the bacteria was otherwise proved in the ordinary way, and also checked by control experiments. Experiments were then made with mixed bacterum coli and typhoid bacilli growths, and although growing together the round yellow coli bacilli could be distinguished from the tendril-like typhoid bacilli. The speaker finally mentioned some cases in which with his method a diagnosis had been made with certainty in twenty hours, whilst Widal's reaction had given no indication, although the disease was already in the second week.

TUBERCULIN TREATMENT.—FURTHER CONTRIBUTIONS. The D. Med. Wochensch. contains the result of observations made in the Victoria Augusta Home and Eberswalde by Dr. Bandelier. Twelve cases were treated by tuberculin, but in none was the treatment employed when fever was present. Koch never claimed that tuberculin would be useful in septic fever, even of tuberculous origin. Patients were kept in bed during the treatment, but during the after treatment they went Only patients completely free from fever then were treated. The guiding principle was to enable the system to bear large doses by gradual increase. Local reaction always consisted in redness, swelling, and some pain, which passed off in a few days. Abscesses never formed. He could not speak as to any actual distinct local reaction at the seat of the disease. The changes took place gradually, and consisted in slow disappearance of the catarrhal symptoms. as well as in diminution of the area of dulness. The general reaction consisted of headache, weakness, heaviness, and dragging in the limbs, &c., a general feeling of unwellness like that of the initial stages of an illness. The symptoms increased with the height of the fever and with the size of the dose of tuberculine, but they were also present when there was no rise of temperature. The first eleven cases were selected with great care, but the physical signs of phthisis were unmistakable. The whole of the cases were undoubtedly influenced beneficially by the tuberculin treatment. By a comparison of the condition at the commencement and the close of the treatment, there was improvement in all, a cure in some. The writer does not deny that other factors contributed to the improvement, but he does not believe that the results would have been the same without the tuberculine treatment.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 4th, 1899.
ALIMENTARY GLYCOSURIA IN THE GRAVID STATE.
In Prof. Schauta's Clinic Hofbauer gave an interesting

lecture to the students on glycosuria in the gravid state. Commencing with the physiological condition and fixing the mean amount of saccharines used up in the animal economy he pointed out how easy a change in the assimilation would induce a form of glycosuria without any other morbid change being present. According to the labours of Strumpell and Strauss this condition is a relative one between the reception and burning of sugar in the organism. When a large amount of sugar was taken into the blood and a state of hyper-glycæmia produced glycosuria was inevitable, although tolerance was another factor to be considered in the renal elimination. The various conditions modifying this temporary form of glycosuria may be classed as neurogenic, toxigenic and febrile. Hofbauer next brought forward a few cases in the gravid state, in which urine had been examined and carefully noted from the beginning of pregnancy. The first case was one where 100 grs. of chemically pure grape sugar had been given early in the morning in tea, sometimes in cognac and water. After administering this quantity of sugar the urine was drawn off by a catheter and carefully examined. Forty-five cases were selected in order to ascertain the normal power of assimilation of sugar in different stages of pregnancy. It is found that the early stage of pregnancy has a constant quantity about the second month, and gradually increases. This positive appearance has led him to recognise in the diagnosis of pregnancy a confirmation of the gravid state. It is not present in the ectopic pregnancy, tubal abortions, or in hematocele formations. It is also negative in mole formations or where the fœtus is dead. He concludes by affirming that the glycosuric test is a physiological condition of the undisturbed and developing ovum. The pathology of the reduced assimilation in the gravid state is attributed to changes in the nerve system and hæmatic circulation. The alteration in the abdominal organs and consequent metabolism are also recognised as factors in its production.

From the experiments on animals, transitory glycosuria is recognised as the result of an injury to the glycogenic organ where there is an insufficient accommodation for hyper-glycemia, and consequently an easy transmission of glucos to the urine. It is interesting to note how this glycogen is produced in the organism during pregnancy. In a normal state of the body, where no pregnancy or disturbance exists, the blood is almost free from glycogen although present in large quantities in pathologica. conditions. Livierato has proved that the blood in pregnancy contains large quantities of glycogen which on approaching the end of the pregnancy is associated with leucocytosis. The colostrum in the gravid state is another phenomenon, somewhat analogous to the glycogen. With Ehrlich's test of potassic iodide mucilage (iodi pur. 10 gramme; potassium iodide 3 grammes; mucilage of acacia 100 grammes) this constituent may be easily determined. Under the microscope the cellular element has the characteristic brown granular colour. There is still a controversy whether this micro-chemical iodide reaction indicates the presence of glycogen, or whether it must be interpreted as another constituent.

The Operating Theatres.

WESTMINSTER HOSPITAL.

EXPLORATION OF THE THYROID FOR DYSPNŒA.—

Mr. DE SANTI operated on a woman, æt. about 55, for enlarged thyroid, causing stridulous breathing and dyspnœa. The patient had had a large symmetrical goitre for many years, but until within the last year had suffered no particular inconvenience therefrom; about that time she commenced to suffer from difficult breathing, which increased, especially when she attempted any active exertion. She was admitted eight months ago under Mr. de Santi, having been sent to him by his colleague, Dr. Murrell; the woman then had a very extensive hard, but well defined, symmetrical goitre, the worst feature of which was that it extended mesially from the thyroid cartilage to the top of the sternum; there was no evidence of malignancy about the swelling. The laryngoscopic appearances showed good movements of cords. There was no dysphagia. When the patient was in the supine position she at once got severe dyspnœa. Mr. de Santi excised under an anæsthetic the middle portion of the isthmus of the thyroid. The wound healed by first intention, and the patient experienced immediate relief. She was discharged, and remained thoroughly comfortable until about six weeks ago, when there was a recurrence of the bad breathing and she was readmitted. The thyroid enlargement was somewhat greater than before, but still well defined, and showing no malignant tendency. An exploration was again made of the central portion, the object being to relieve tension and possibly perform tracheotomy; the incision extended to the top of the sternum, and a careful exploration was made in the mid-line along the whole length of the wound; the trachea was not to be found mesially, but on examining further it was discovered embedded in a mass of thyroid tissue, and well over to the right side of the mid-line. The division of the cervical fascia, and of the mesial portion of the thyroid swelling gave so much relief under the anæsthetic at the time that nothing further was attempted, Mr. de Santi said and the wound was closed. that the case was illustrative of the immense difficulty that may arise when a surgeon is suddenly called upon in such cases to perform tracheotomy; in this particular instance not only was the trachea considerably deflected from the middle line, but it was very much narrowed by lateral compression. Moreover, the central part of the tumour had extended to below the level of the top of the sternum, making it almost impossible to perform a low tracheotomy. It was out of the question to attempt in so bad a subject the removal of half the thyroid, and the only measures that appeared to offer any hope of relief to the patient were those that were carried out. The patient made a good recovery from the operation, but about a fortnight later suddenly got light-headed, and died from an attack of cardiac syncope. At the post-mortem a very extensive bi-lateral goitre was discovered which implicated the trachea and œsophagus; the trachea was for some distance not only displaced to the right, but very considerably compressed from side so side. The œsophagus was also found compressed. The central portion of the goitre extended well down into the anterior mediastinum, and on examination of the deeper and lower part of the neck, a few suspicious-looking glands were discovered; these were microscoped by the pathologist, and found to show commencing malignant disease.

ST. THOMAS'S HOSPITAL.

GASTROSTOMY BY ALBERT'S METHOD .- Mr. BATTLE

operated on a married woman, æt. about 53, who had been in his out-patient department for some time, suffer ing from difficulty in swallowing. She had noticed the difficulty for some weeks, and it had gradually increased until no solid food could be swallowed. Examination with a bougie showed no evident obstruction, although its passage caused some pain behind the upper part of the sternum. There was no blood on the instrument when it was withdrawn. When she swallowed she complained that the food appeared to stick behind the upper part of her breastbone, but there was nothing abnormal to be discovered either in the thorax or in the glands of the lower part of the neck. She had lost strength, but was fairly vigorous, and her appetite was good. Treatment in the out-patient department had relieved her for a time, but the condition became gradually worse until no solid food at all could be swallowed, and after admission to the hospital, when obstruction was more definitely felt, the operation of gastrostomy was advised. This was performed in the following way. An incision about two and a half inches in length was made in the left rectus muscle and carried through the posterior layer of the muscle sheath until the peritoneum was opened; the stomach was easily found and drawn through the wound to some extent until a cone-shaped portion as near the cardiac end as possible had been held up-The peritoneum and rectus sheath were then united by means of a continuous stitch to the base of The remainder of the wound was this projection. then closed. The apex of the cone was then carried upwards under the skin and subcutaneous tissue of the lower part of the chest, and made to protrude through an incision in the skin about two inches from the upper end of the first incision; it was then sutured there. So far the stitches had not penetrated beyond the submucous coat, but after the separate suturing of the rectus muscle and of the skin of the lower wound, four stitches were placed in the upper portion of the stomach wall, and after the stomach had been opened these were tied so as to hold the edges of the opening back. A No. 4 catheter was then passed into the stomach and secured in position; cyanide gauze dressing was applied. The advantages claimed for this method of operation, Mr. Battle said, are that there is less likelihood of regurgitation from its employment, and to this the length of passage between the opening in the stomach and the point where it passes through the muscle, as well as the contraction of the muscle itself, are supposed to contribute. another advantage in the fact that the stomach is opened at a distance from the peritoneum, and is opened early so that the benefits of the operation are at once experienced. He remarked that he had previously performed the same operation, and the result had been satisfactory. The case just operated on was also interesting in the fact that the patient was a female; epithelioma of the œsophagus, or, inde d, auy malignant structure in that situation, being very rare in that sex. The patient was fed through the catheter which protruded through the dressing, and up to the present has progressed extremely well, having had a normal temperature, complete absence of pain and great relief from the sensation of hunger; her expression is much improved, and she looks much stouter in the face.

WEDNESDAY, MARCH 8, 1899.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

On this day week Mr. MacArdle, of St. Vincent's Hospital, Dublin, opened, as President, the session of the Medical Society of the Catholic University with an address which, in a general way, would not deserve notice from us, it being only a reiteration for the thousandth time of the politico-religious "screech" about anti-catholic intolerance of which Irish readers are so weary. We are called upon, however, to analyse Mr. MacArdle's address because in it his blatant oratory was chiefly devoted to villifying the Irish College of Surgeons, whose "reputation, honour, and dignity" he, as a Fellow, strove to uphold. Putting aside the orator for a moment we cannot refrain from expressing surprise that the authorities of the Catholic University should have countenanced a scurrilous attack on a sister institution with which it has always been on the most friendly terms, and that any Fellow or ex-Fellow should, by his presence and silence, have tolerated the proceeding. The charge of Mr. MacArdle against his College was that—

"Out of the numerous class of Catholic students, many of them distinguished, the College had failed to select one to occupy any position of trust or emolument and when they came to examine the encouragement given to the (Catholic) students who thus supported (the College) they found that of all the offices in (its) gift not one was in the hands of our co-religionists."

We shall save time by saying, at once, that these statements are demonstrably, totally inaccurate and misleading, and that there is probably no medical institution less open to the odious charge which Mr. MacArdle makes than the College which he

abuses. To begin with, the candidates for collegiate examinations, as a matter of fact their names, much less their religion, are not known to the examiners. Very many of them, and the College says, the more the better, are Catholics, and we challenge Mr. MacArdle to substantiate his suggestion that they are not on a perfect examinational equality with those of any other religion. Next. as regards the Fellowship of the College, we emphatically repeat the same challenge. Any licentiate can become a Fellow by passing an examination of a higher standard. No one can stop him if he knows his work. least of all does the College want to do so, and, as a matter of fact, a large and increasing number of Catholic diplomates obtain the Fellowship. There is not, here, as in some other Colleges, any selection of Fellows, by Catholic or otherwise. It is, indeed, a subject of regret that many do not take the Fellowship, and that many hospital and school teachers in Dublin do not hold it. but this arises from circumstances over which the College has no control. For the past forty years the whole of the Queen's College students have gravitated either to the Queen's University or to its successor, the Royal University, or have migrated to Scotland. This has arisen chiefly through local school association and a saving of money. even Mr. MacArdle will scarcely aver religion has anything to do with it. But the fact remains that the number of Catholic Fellows who are in a position to offer themselves for collegiate office is relatively few. Yet of those that are available almost every one (save Mr. MacArdle, who complains that he did not get even one vote) has served or is serving the College. For a seat on the College Council every Fellow can offer himself, once a year, to the 280 electors, and no power can prevent his election if his character and professional standing recommend him to these Catholic electors. As a fact, four Catholic surgeons are now Councillors, of whom one has been President, and two others Examiners. Mr. MacArdle's own colleague at St. Vincent's was both Councillor and Examiner, and, we believe, might be so again if he wished. The other specially Catholic hospital, the "Mater," contributes two of its surgeons -one of whom has been an Examiner for several years — Jervis Street Hospital — also supposed to be Catholic in sentiment-contributes two Catholics of its staff, one of whom has been an Examiner. The Professor of Anatomy in the Catholic University School is now an Examiner, and the Professor of Physiology was so for several years, while three of the Catholic learners of Mr. MacArdle, two of whom have ceased to be Fellows of the College, were all examiners in their time. As to Professorships in the College school—the only other offices of emolument—we may remind Mr-MacArdle that Dr. E. D. Mapother was both Professor and Councillor for many years. That only one new election of a Catholic or anyone else to a Professorship arises from the fact that there has been no vacancy in any chair-save that one

the Carmichal the amalgamation of — since School with the School College and Ledwich We hope we have now ten years ago. ciently refuted Mr. MacArdle's rash statements and calumnious inuendos, and that he may now appreciate the fact that even the making of politico-religious capital does not justify an orator in saying "the thing which is not."

A CHARITY PRIMROSE LEAGUE.

Ir anything were really wanting to show that another mistake had been made in connection with the Prince of Wales's Hospital Fund, that evidence is amply supplied by the chilling silence with which the inauguration of the so-called "League of Mercy" has been received by the public Press, from the Times downwards. It is remarkable and curiously significant that this proposal, to which Her Majesty the Queen, together with the Prince and Princess of Wales, had announced their support, should have been so received. We fear that it means that the Prince cannot be congratulated upon those who are responsible for advising him as to the exploitation of schemes designed for the benefit of hospital charities. Thus it is impossible to avoid expressing sorrow for the Prince in the circumstance in which he is placed. With every possible intention of doing everything in his power to advance their interests, he is asked to lend his name and support to impracticable schemes which from the first have no chance of success. We are grieved, for His Royal Highness's sake, to have to admit that his Hospital Fund has proved to be a failure; it is a matter of regret to have to record that the Hospital Stamps Scheme with its "ministering children" enterprise has failed to infuse life into the Fund, and lastly it is obvious that to make a further attempt to bolster up a failure by an impossible and impractical organisation such as the "League of Mercy," the ending of which is likely to be rather more disastrous than anything which the Prince's advisers have attempted before, is to follow a policy which no sane person could possibly commend. There would have been no need for such tinkering in order to maintain the success of the Fund to which His Royal Highness had lent his name had administration commanded \mathbf{the} confidence designed to assistwhom it was of those But from the first it was regarded askance by those in authority in the hospital world. There were many, for example, well known as workers and organisers in hospitals, men to reckon with in their sphere of work, who were severely left out in the cold when the announcement of the scheme was made. Thus the promoters of the Fund courted opposition before the work of the Fund was commenced, and it is not unnatural to believe that that opposition, as time progressed, has been fostered, and has had not a little to do with the present disappointing position to which the Fund has reached. But all this might have been otherwise had the Prince headed a movement which was accepted from the first as a national, as apart from a one man scheme. This is some-

what the position assumed by the Daily News, whose trenchant article upon the "Prince's Primrose League" has attracted so much attention. "The hospital stamps," says our contemporary, "the League of Mercy, the dependence on the name of the Prince of Wales, should be given up frankly, completely, and at once, and the Prince should be invited to place himself at the head of a movement for a thorough review and reform of hospital administration. When the hospitals are under a central and representative board, and are more amenable to public criticism and control, the money for their successful working will not be wanting; the Prince of Wales's Hospital Fund will not languish." Herein, after all, is possibly the solution to the question. The hospital world in London is made up of so many rival interests, that the only chance for any successful working of the same, at all events so far as the distribution of public funds is concerned, is, perhaps, the organisation of a central authority composed of representatives from each charity. There would then be no fear of each hospital, special and general, not receiving its due; there would be no room for favouritism with regard to the distribution of public funds; confidence would be felt in the decisions of such a board, and the public, imbued with the same confidence, would scarcely fail to do their part in providing the funds. The proposal of having a Central Hospital Board for London was, it will be remembered, submitted to the Executive Council of the Prince of Wales's Hospital Fund, and, as was to have been expected, the Council declined to have anything to do with it, no doubt because it emanated from the Charity Organisation Society, with whom Sir Henry Burdett has for long had variances. But since then the Executive Council aforesaid, having failed to make a success of the Prince of Wales's Fund, their authoritative control over the Hospitals has dwindled almost to vanishing point, and thus has made plainer than before that some central administrative organisation in the interests of these charities is needed.

PREMATURE BURIAL.

Among a multitude of popular errors there is probably none more widely spread and more deeply rooted than the belief in the frequency of live burial. Of recent years the subject has been fanned from a smouldering ember to a hot flame in various parts of the world, chiefly, it may be remarked, by folk who are interested in furnishing patent coffins, in the sale of special literature, in the paid certification of deaths, or in other ways productive of direct or in. direct pecuniary benefit. The possibility which they maintain is terrible indeed, and one certain to grip tenaciously the imaginations of folk whose faith is not founded on logic. In America the movement been so industriously engineered that a Bill is actually being introduced into the Legislature with the object of preventing premature burial. The ways and means by which it is proposed to compass that end are such as might be expected from men who have accepted the theory of so grim and ghastly

an occurrence. Provision is made for the retention of a supposed dead body for at least twelve hours in a well ventilated public mortuary chamber open to inspection. The most important innovation, however, is that which demands from the medical attendant or the coroner a death certificate making specific mention of the following signs of death: -(1) Permanent cessation of respiration and circulation; (2) purple discoloration of the dependent parts of the body; (3) absence of blistering around a part of the skin touched with a red-hot iron; (4) rigor mortis; (5) signs of decomposition. Exceptions are made as to the exposure of those dead from certain communicable diseases, and also when vital organs are obviously destroyed or the body has been discovered in an advanced state of putrefaction. There is nothing in these proposals which reasonable persons anywhere need hesitate to accept; indeed, for that matter, the institution of a universal mortuary system in the United Kingdom would be a most desirable step in the right direction. Nor would they refuse any measure that rendered careful personal and skilled inspection of a dead body imperative before the granting of a certificate of death. At the same time, it seems likely that the whole theory of the frequent occurrence of premature burial is a bogey, a popular error, an imaginative myth that melts away before the prosaic touch of scientific investigation. A year or two ago a small volume was published in London under the title of "Premature Burial: Fact or Fiction?" The author did not deny the possibility of the occurrence of live burial, but altogether doubted its probability. He further analysed the literature of the subject, and asserted positively that of the many hundreds of reported cases he could not find a single one trustworthy from a scientific point of view. He pointed out the many fallacies that surrounded the subject, such as the impossibility of life being sustained for any length of time inside an airtight coffin, and the numerous ways in which the position of a body might be disturbed in a coffin between death and burial; and he showed that the cases of resuscitation, if accepted, went to prove the difficulty of burial under such circumstances. Briefly stated, his main conclusion was that while no cases of premature burial could be taken as established, yet that under certain conditions demanding rapid burial it might be remotely possible, but at the same time it became practically out of the question after the supposed corpse had been subjected to a skilled medical examination. We allude to this little book because it is the only one with which we are acquainted that deals with the matter from a scientific standpoint. Its contentions have never been upset, indeed, the only attempts to meet them have been by untrained writers who have trusted to unsupported contradictions, and to the further testimony of hearsay and unsifted evidence which would not be accepted in any court of law. The course that will probably be adopted by the American legislature as regards the above-mentioned Bill is not within our knowledge,

but, if passed, it will be by no means the first occasion upon which a knot of agitators has diverted the current of legislation into non-scientific channels although, fortunately, in this case, no actual harm is likely to ensue. For some years past the introduction of a similar measure has been hinted at in certain quarters in our own country, but it is to be hoped that Parliament will stop at the establishment of public mortuaries and the much needed strengthening Of late not a little has been of death certificates. heard of the coming millennium of social legis-When that happy era is at hand it may be pretty safely predicted that a new Medical Act will occupy a foremost place in the scheme of reform, wherein the other points mentioned will also figure prominently. Meanwhile, the timorous citizen may be advised to disregard the bogey of premature burial, and the timorous legislator to exclude it from his list of matters that press for attention in the field of practical politics.

Rotes on Current Topics.

Nitrous Oxide as an Anæsthetic.

NITROUS oxide is a very useful anæsthetic, but it is generally regarded as an agent which does not lend itself to operations requiring prolonged unconscious-Recent researches show that this view is founded on an imperfect appreciation of its properties, for it has been demonstrated that by a judicious and carefully regulated admixture of oxygen, or even of air, the anæsthetic effect can be maintained for an indefinite period. Moreover, this admixture removes the asphyxial phenomena which constitute the only danger which the use of this agent entails. It is evident that we have not reached finality in the matter of general anæsthetics, for there are many alternative ways of inducing insensitiveness to pain. Pure nitrogen and hydrogen, for example, produce anæsthetic effects very similar to those following the administration of nitrous oxide. It is a curious fact that the addition of about 5 per cent. of oxygen gets rid of the lividity and stertorous breathing which characterise the effects of nitrous oxide as usually given, and as the anæsthetic effect is not thereby lessened, we may infer that nitrous oxide does not produce its effect merely by depriving the nervous centres of their quota of oxygen, but in virtue of a specific action. It is suggested that it leads to an accumulation of carbonic acid in the blood sufficient to deprive the sensorium of its functional activity in spite of a provision of the element oxygen. Though possibly less convenient of administration than the anæsthetics in general use, the fact remains that nitrous oxide is by far the safest general anæsthetic we possess, and if a simple and not too expensive apparatus could be devised for its administration in combination with measured quantities of air or oxygen its more general use in surgery might conceivably do something to reduce the present lamentable mortality from anæsthetic narcosis. Neverthe

less it does not appear likely to displace chloroform which, when properly administered, is safe enough for all practical purposes. When the profession and the public have come to regard every death under chloroform as entailing a presumption of careless or unskilled administration only to be foregone on proof of adequate experience, and the employment of the best apparatus procurable, the mortality under this head will, we doubt not, promptly fall, if not to zero, at any rate to the extent of becoming a negligeable quantity.

The Right of Prosecution.

In the course of a reply to Mr. McNeill on certain statements charging Dr. Hime with practising vivisection, it was stated by the representative of the Home Office that the performance of an experiment upon an animal calculated to give pain, by a person without a licence, was an offence under the ordinary law, in respect of which anyone might prosecute. We were under the impression that under the Vivisection Act the right of presecution was vested in the Home Secretary, but closer scrutiny shows that this restriction only applies to proceedings against licensed persons, and amateur vivisectors unprovided with a licence would render themselves liable to prosecution under the ordinary law for the protection of animals. They would presumably be charged with "causing unnecessary pain," but the magistrate would have to decide whether such a thing as an inoculation with a specified object in view amounted to the infliction of unnecessary pain, and we feel sure that the average magistrate would hesitate to place the scientific investigator on the same footing as the irate coster who twists off his donkey's tail, or the wanton rough who sets his dog to worry a cat. We are not likely to see this point settled in a hurry, because, on the rare occasions on which a private and unlicensed person infringes the Act, he does not carry out his experiments on the doorstep for the information of the man in the street, but, in Biblical language, goes into his closet and shuts the door.

Operations for Enlarged Prostate..

AT a recent meeting of the Clinical Society Mr. J. R. Lunn read notes of a series of six cases of castration for enlarged prostate with results which ought to go far to popularise recourse to what, so far, may lay claim to be the only surgical procedure which holds out any substantial prospect to these unfortunate patients of permanent relief from the terrible sufferings and permanent discomfort entailed by an enlarged prostate. There is, of course, a reverse to the medal. We cannot with impunity temper with glands which, in addition to their ordinary secretions, doubtless exert a far-reaching effect on the organism by means of the internal secretions of which Claude Bernard was the first to suspect the existence. Although Mr. Lunn does not appear to have observed any instance of mental trouble as a sequel of the operation, other surgeons have been less fortunate, and, in a certain proportion of the cases, mental disturbance accompanies or

follows vesical relief. Even when a reduction in the size of the prostate has been attempted by this operation the necessity for measures having for object the removal of the mechanical conditions created by past difficulties remains. As a rule considerable damage has been inflicted on the genito-urinary tract before this dernier ressort is consented to, and unless these are met, the supervention of renal disease is but too likely.

The Asepticity of Urine.

In former days it used always to be assumed that the extravasation of urine into the peritoneal cavity meant the development of an attack of acute peritonitis. Later experience, however, has taught us that this is by no means the case. Whether or not the peritoneal inflammation begins depends upon the character of the urine. If, for example, a ruptured bladder discharges healthy aseptic urine into the peritoneal cavity, no inflammation occurs; in other words, everything seems to depend upon the asepticity of the urine. Tuffier was the first to draw attention to this fact, and cases have been recorded in which the proof of his statement is placed beyond dispute Confirmatory too of the fact is the case recently published of a farmer who was kicked by a horse, after having been thrown, as the result of which he sustained an intraperitoneal rupture of his distended bladder, followed by extravasation of the urine into the peritoneal cavity. The perforation presumably was a small one, and, occurring at the time when the bladder was very much distended, it was closed by the contraction of the empty organ, and rapidly healed. The man recovered without a bad symptom. the whole of the extravasated urine having been absorbed by the peritoneum. Such cases as these are gratifying examples of what Nature can do when she is so disposed.

The Flash Point Crusade.

WE are glad to see that the Star is still carrying on its able campaign against the dangerous low flash American mineral oil sold in this country. There must be no compromise in the matter. The public should understand that nothing short of a minimum flash point of 100 degs. F. is safe, so far as petroleum is concerned. It has been proved beyond dispute that the present low minimum flash point of 73 degs. F. is deadly dangerous to the consumer, apart from the construction of the lamp, and the only plea which can be urged in favour of its retention is one solely advanced in the interests of the monopolists by whom the oil is supplied. The Standard Oil Company, we understand from the Star, having taken alarm at Mr. Reckitt's Bill which is set down for second reading in the House of Commons on the 15th instant, are bringing pressure to bear upon oil vendors in order to cajole them into petitioning the Government not to raise the flash point to 100 degs. F., as the Bill proposes to do. It is to be trusted that the trade will do nothing of the sort. This attempt by the company to influence their customers adversely will probably defeat the object which the former are

seeking to obtain. In the midst of all the discussion upon the subject it is difficult to understand the position assumed by the Government. The chairman of the Petroleum Committee, Mr. Jesse Collings, as is known, has opposed the proposal to raise the flash point, but why should the Government seem to be favourable to this view also? Surely enough evidence has been brought forward to show the evil that the low flash petroleum is capable of producing. Moreover, it is iniquitous that the lives of the people in this country should be imperilled by the sale of an oil which is not allowed to be sold in America.

"The Cry of the Children."

It was wise on the part of Lord Salisbury to leave the "Children's Bill" to the decision of Parliament. Consequently the second reading of the Bill was carried by a very decisive majority of 258, on Wednesday last. Convinced of the great physical and educational evils inseparable from the half-time employment in factories, it was time this step should be taken. We may now hope, after the commanding success of Mr. Robson's Bill for raising the age of the children from eleven to twelve, the Bill will be placed on the Statute Book on a very early day. The measure is a necessity if this country is to compete successfully with France, Germany, Switzerland, and other countries in the commercial world, and because the physical deterioration arising out of the half-time systems means stunting and weakening the raw material of our Army and Navy. Indeed, the system of "half-time"—that is, of setting young children to premature toil-is cruel as well as fundamentally wrong. We, therefore, heartily endorse the sentiment expressed in Parliament by the author of the Bill, that "No nation can expect to prosper by hindering the physical and mental development of the young."

Plymouth Guardians and the Local Government Board.

As the world knows, the policy of the Local Government Board has hitherto been to interfere as little as possible with matters of local administration. As a rule it is only when some scandal has stirred up the indignation of the public that the central bureau has taken decisive action—that is to say, so far as a brave show of authority goes. But local bodies have learned to disregard the brutum fulmen of Whitehall as an empty threat to be laughed at and evaded. A case in point may now be witnessed at Plymouth, where the condition of the Poor-law infirmary has long been notoriously inadequate and bad. For two years the Guardians have played the familiar parochial game of battledore and shuttlecock with the central Board, until the latter has lost patience and addressed a peremptory letter calling upon the Guardians forthwith to provide the necessary accommodation. The results of this official order has been a simple declaration of defiance on the part of most of the local administrators, whose chairman openly advocated a policy of masterly inactivity. So far as can be gathered, the chief objection to rebuilding is the cost, which will be about £50,000; but, of course, that is no argument for failure to discharge a legal duty. From the uncontradicted statements of Guardians, the present infirmary is inadequate both in space and in construction; in fact, a number of patients have to sleep in the main workhouse buildings, and one lunatic sleeps on the floor, while the bathing arrangements are described as "scandalous." Of late years the Poor-law administration of the West of England has gained an unenviable notoriety, and it is somewhat curious that Guardians should court further publicity in similar unfavourable directions. The next move of the Local Government Board will be awaited with some interest.

The Irish Medical Association Reform Meeting.

WE publish in our Irish Supplement of this day an extended report of the aggregate meeting of the profession held in the Irish College of Surgeons on Thursday last, and organised by the Association. We may truthfully describe the meeting as an unequivocal success. It was admirably administered by Sir Thornley Stoker, the President; was distinguished by the presence and by the advocacy of its objects by the Presidents of the Colleges and other leaders of public opinion on professional affairs; was the largest gathering of Poor-law Medical Officers which ever assembled in the College or elsewhere; and was characterised throughout by the calmness and argumentative discretion of the speakers, none, of whom asked for more, in the way of reform, than might reasonably be granted. Such a meeting must have, and we hope, has already had an excellent public effect. and will, we doubt not, do much to bring the authorities into line with the reasonable aspirations of the Poor-law Medical Officers of Ireland.

Modern Views on Graves' Disease.

EXOPHTHALMIC goitre, or Graves' disease, is by no means the implacable morbid entity that is pictured in most text-books. On the contrary, it would seem that a very large proportion of the patients suffering from this malady sooner or later undergo partial spontaneous recovery. When death does occur therefrom, it usually takes place during the first eighteen months, and in view of the inefficacy of treatment, it is comforting to recollect that Nature has a way of her own of discarding the most troublesome symptoms. Of these, palpitation is certainly the most constant, and it is precisely the one which most uniformly undergoes spontaneous subsidence. The outward and visible manifestations in the shap? of enlarged thyroid and prominent eyes, on the other hand, rarely do more than to cease developing. The pathology of the disease is still shrouded in much obscurity. The hyper-secretion of thyroid juice, to which are ascribed the clinical manifestations of the disturbance, may after all only be an effect of an underlaying disorganisation of the nervous system. Certain it is that the results of partial removal of the gland do not give better results than less drastic

measures, while the intervention is of itself a highly hazardous proceeding.

Myths About the Mahdi.

THE discussion which has been taking place in the House of Commons about the late eminent prophet of the Devrishes has not been edifying as an example of British intelligence. Great umbrage was displayed at the treatment meted out to the Mahdi's body by the Sirdar, and great pains were taken in the endeavour to discover what had become of his skull. The opinion still seems to prevail among a certain class of people that the Mahdi's skull is not now lying peacefully deposed at the bottom of the Nile; on the other hand, the conviction seems to be firmly implanted in the minds of some persons that it is now adorning the craniological collection in the Hunterian Museum at the Royal College of Surgeons, England. As a matter of fact, there is no evidence to show that the Mahdi's skull is not exactly in the place to which the Sirdar ordered it to be consigned, and the officials at the college aforesaid are just as ignorant of its whereabouts as probably the Mahdi is now himself. Again, someone is reported to have handed round to the guests at a dinner the other day one of the Mahdi's little fingers. There is, however, probably just as much truth in this as in the other canards about which so much unnecessary fuss has been made regarding the defunct prophet. But in all these transcendental displays of wounded sentiment no one seems to have recalled what the Mahdi did to the body of our great countryman, General Gordon. In their efforts to make political capital out of a necessary incident in the Soudan campaign, the busy-bodies, both within and outside the House of Commons, have overlooked the fact that nothing which may have been done with the Mahdi's remains could equal the savage indignities heaped upon the body of one of England's greatest sons whom fate placed in the power of the Mahdi.

The Health of the Pope.

THE surgical intervention which the medical advisers of his Holiness thought necessary to practise last week, consisted in the removal, through a five inch incision, of a sebaceous cyst, the size of an orange, situated over the iliac bone on one The cyst had been slowly increasing in size for the last twenty-five years, but beyond preventing its illustrious possessor from sleeping on that side, it had seldom caused any trouble or inconvenience. As is not uncommon with this kind of cyst, its longstanding quiescence suddenly gave place to acute inflammation, causing a disquieting rise of temperature and considerable local distress. As the use of a general anæsthetic was obviously unadvisable in a patient nearly ninety years of age, sensation was diminished by the use of cocaine and a refrigerant, and the inflamed cyst, including its envelope, was removed without difficulty by Dr. Mazzoni. temperature at once returned to normal, and in the absence of septic complications, no evil results are to be apprehended.

A Reported Antitoxin for Pneumonia.

THE recent life-and-death struggle in which Mr. Rudyard Kipling has so happily gained the upper hand will focus for a time the minds of mankind generally upon the why and wherefore of pneumonia. The pathology of that scourge has been recently discussed in these columns, and the only reference that need now be made in that direction is the causative nature, in many if not in all cases, of a specific pneumo-coccus bacillus. With regard to that microbe a notable announcement was made last week by a disciple of Koch, Professor Wasserman, who hopes that he has discovered an antitoxin that may be curative of pneumonia. From the reports which are at hand it seems that the Professor first inoculated rabbits with active pneumococcic cultures. After prolonged experiments he discovered that the antitoxin produced in the animal was elaborated in the red marrow of the bones, so that red marrow taken from a human subject dead from pneumonia, and used as serum, will cure mice infected with that disease. Whether this observation will be upheld in the long run or not, there is little doubt that, sooner or later, in some such way the ravages of the deadly pneumococcus will be set at naught by the scientific medical man. It is well, however, to accept news of this kind with a good deal of caution, for it is the way of mankind eagerly to clinch the belief of whatever it wishes to believe. The wild excitement that ran through all ranks and conditions of society, medical and non-medical, rich and poor, at the announcement of Koch's supposed remedy for tuberculosis, will remain a standing memento of the unwisdom of accepting a theory that has not been subjected to the stern test of everyday practice.

Prize Fight v. Boxing Contest.

Those who abide by the law will rejoice over the decision of the Glasgow Bailies that the modern match with light gloves is no mere boxing contest. Two men named Dobbs and McDonald were charged with assault and breach of the peace on February 22nd by engaging in a prize fight in the city mentioned. The police evidence testified to the fierce and determined nature of the conflict. In the second round Dobbs knocked McDonald down twice, on one occasion through the ropes and off the platform. The fighters' object was to knock each other senseless, and the encounter could not have lasted for the stipulated twenty rounds. The truth of the last statement has since been abundantly upheld at Newcastle, where the same two pugilists met while under remand from the police-court. The Scotchman was beaten before the second round by some tremendous knock-down blows. All this brutality reads like a newspaper cutting from the barbarous days of our forefathers, when prize-fighting was a fashionable art. The milder manners of recent generations, however, have changed all that, and have declared these brutal encounters illegal. In the name of commonsense, then, let the police stop the revival of the prizefight under the specious pretence of being fought with

light boxing-gloves, which afford about as much protection as would a pair of ordinary riding gloves. At the same time no one wants to hinder the healthy sport of boxing with ordinary gloves. Surely some rules increasing the weight of gloves, and making glove fights for money prizes or wagers illegal, would go far to scotch the spurious glove fight.

Suicide in a Hospital Padded Room.

THE padded room of the London Hospital seems bentupon winning its way into notoriety. A few weeks ago it witnessed the death of a patient suffering from delirium tremens, and bound hand and foot in some form of mediæval shackles. Now, it has been brought to the coroner's notice as the scene of a suicide of a temporarily insane patient. From the evidence it appeared that the deceased cut his throat, and that it was within the knowledge of the two male attendants that he had a knife in his possession. It would be interesting to learn what were the qualifications of the men to whom the arduous and responsible duty of attendance was entrusted. That they were unworthy of the confidence bestowed on them is to be gathered from the foreman's rider to the verdict: "We unanimously wish to pass a vote of censure on the attendants Green and Clark, as we do not believe a word they say."

The Death of Dr. Boyd.

THERE are several points worthy of attention in connection with the lamentable catastrophe which entailed the sacrifice of a valuable life. First and foremost, is the carelessness which characterised the fatal error. No precautions can ever avail against accidents of this kind if patients will not even take the trouble to look at the bottle and its label, and in this instance, if the wrappers had been removed, as they normally would be, the error would have been impossible. Another striking feature is the extraordinary rapidity with which the acid produced irreparable mischief. There was immediate warning of the mistake and every opportunity, had skilled aid been promptly forthcoming, for antidotal measures, a dose of oil, or milk, or white of egg, or Epsom salts, and the mischief might have been limited to the local damage. What a splendid opportunity for "first aid" intervention! The occurrence serves to emphasize the singularly deadly nature of the poison which the Government, with inexplicable obstinacy, declines to safeguard. It suggests, moreover, the desirability of insisting that the label on all bottles containing a deadly poison shall bear directions for treatment in the event of a mishap. The extra cost of such labels would be trifling, and the gain of time all important. An additional precaution would be to have all poison bottles triangular in shape, thus calling attention in a way that could not possibly be misinterpreted to the nature of their contents.

In 1870, there were 527 medical women in the United States; in 1897 there were 6,882.

The Medical Society of Victoria.

The Medical Society of Victoria, which has elected Sir T. N. Fitz-Gerald as its president for the current year, is a very flourishing colonial medical body. Its membership now amounts to a total of 276, and thus entitles it to be regarded as one of the first—if not the first—of the societies among the British Colonies, devoted to medical work. Our contemporary, the Intercolonial Medical Journal, the organ of the Society, publishes in its January issue a long list of valuable communications read at the Society's meetings during the past year, and a reference to the treasurer's report shows that the balance in favour of the Society now stands at upwards of £1,130. We congratulate our confreres in Victoria upon their successful organisation.

THE second reading of the "Sale of Food and Drugs Bill" was moved by the Secretary of the Board of Agriculture, Mr. Walter Long, on Monday night, and stood adjourned. The debate is expected to be a prolonged one, much opposition being already manifested to some of its provisions.

PERSONAL.

SURGEON-GEN. MUIE has been selected as Deputy Director-General of the Army Medical Service.

SIR T. N. FITZGERALD has been elected President of the Medical Society of Victoria for the current year.

MR. E. F. ELIOT, F.R.C.S., L.R.C.P.E., F.F.P.S., &c., has been appointed a magistrate for the County Borough of Southampton.

Mr. W. F. R. Weldon, F.R.S., has been elected Linacre Professor of Comparative Anatomy at Oxford in succession to Professor Ray Lankester.

Dr. Ray, who for the past thirty years has been in practice in Dulwich, was last week presented with a silver bowl and salver, together with a cheque for £116, subscribed for by his patients and friends in the district.

PROFESSOR RAY LANKESTER, Superintendent of the Natural History Museum, South Kensington, has been appointed a corresponding member for the Anatomical and Zoological section of the Academy of Medicine in Paris.

WE understand that the Senate of the University of Aberdeen has decided to confer the honorary degree of LL.D. on Dr. James F. Goodhart, Physician to Guy's Hospital, a former graduate of the University with highest honours.

LORD ROSEBERY has been nominated by the Liberal section of students of the Glasgow University for the Lord Rectorship. The Conservative section have not yet decided on their candidate, but are expected to settle the point this week.

SURGEON-GENERAL ALBERT GORE, who has recently retired, with much distinction, from the position of Principal Medical Officer of the Indian Army, and on whom devolved the entire medical management of the

extremely difficult campaign in North-West India, is temporarily residing in Kingstown.

THE Duke and Duchess of Fife visited the Hospital for Sick Children, Great Ormond Street, on Thursday last. The Duchess gave toys to 154 children in the wards, and the Duke gave £100 towards the £20,000 required to complete the purchase of the Nurses' House and the garden for the sick children.

THE fact that a member of our profession has reached the patriarchal age of a century is of such rarity that we are prone to call attention thereto. What is more remarkable in the present instance is that Surgeon-Major John Bouron served the best years of his life with the Army in India, dying at Brighton on Sunday last in the 101st year of his age.

Scotland.

FROM OUR OWN CORRESPONDENT.

THE GLASGOW CORPORATION AND MEDICAL FEES. Recently a Glasgow practitioner became dissatisfied with a fee of five guineas for some work which he had done on behalf of the Corporation, and returned the cheque, accompanied by a note, "with compliments." The inci-dent was duly reported to the committee interested, and they agreed to accept the gentleman's compliments and cancel the cheque. Probably the amount of work done would have been badly remunerated by the acceptance of this small cheque, but it is proverbial that the Glasgow Corporation does not consider medical men's time as of much value. Some time ago a medical man was sent for by the police in a case of accident, the best part of a whole day was taken up, an exhaustive report written, as well as evidence before officials. After a while a modest account for the large sum of one guines was sent in, to which the Watching and Lighting Committee replied that if the charge had been, say, 3s. 6d. they might have considered it, and as no written order was sent to the medical man, even although summoned by the police on the beat, they would not entertain for a moment any indebtedness, and the claim was accordingly disallowed. Let Glasgow flourish !

CHAIR OF ZOOLOGY AT ABERDEEN.—A testimonial in the form of a letter is being largely signed by the professors and medical students in the Glasgow University in favour of the candidature of Mr. James Rankine, B.Sc., M.B.C.M., Professor Young's assistant, for the vacancy caused by the death of Professor Nicholson. Mr. Rankine has been for several years assistant and demonstrator in the Glasgow University under Professor Young. He graduated B.Sc. in 1892 with first-class honours in zoology and botany, being awarded at the same time the George A. Clark Scholarship in Natural Science, of the value of £180, tenable for four years. He received his M.B.C.M. in July, 1897, with commendation.

GOVERNMENT LUNACY BOARD, SCOTLAND .- As Dr. Sutherland is likely to be raised to a higher grade on the Board, there is a rush of candidates for the post of Deputy Lunacy Commissioner. The appointment is in the hands of the Secretary of State for Scotland, and a great deal of canvassing is being carried on and wirepulling done by certain Glasgow physicians, in order to secure the coveted post. Of course, influence will carry the day, and if a Glasgow man does not secure the appointment there will be great wailing and gnashing of teeth, in some instances of gums. It must be admitted that lately Glasgow men have been very fortunate in securing comfortable and lucrative appointments, and if their good luck continues, they will, after a while, expect to fill any vacancy to the exclusion of all others, as a matter of right.

Parliamentary Aews.

Among the new Bills introduced is "The Inebriates Act Amendment Bill," the object whereof, comprised in two clauses, is to remedy omissions in last year's Act. It has been found necessary to provide that the expense of prosecutions under Section II. should be payable as in cases of felony, while the second clause gives power to deal summarily with breaches of the regulations made by the Secretary of State with respect to inebriate reformatories. The Home Secretary promised to consider the appointment of a lady inspector should this

appear necessary.
The Sale of Food and Drugs Act Amendment Bill is before the House. The first part deals with dairy produce. The Margarine Act is extended and rendered more precise, and cumulative penalties are proposed in connection with the adulteration of food and drugs

In reply to a question by Mr. W. Ambrose, Mr. Long said that no case of rabies was known to have occurred in Middlesex during the past six months, but he did not consider that the muzzling order at present in force in that and other parts of the Metropolitan Police District could as yet be safely withdrawn.

In reply to a question by Dr. Farquharson, it was stated that an increased establishment had been given to all companies of the Volunteer Medical Staff Corps, in order to complete the personnel for transport sections. There was no present intention of making any alteration in the rank of Volunteer Medical Officers. The question of the reorganisation of the Volunteer infantry bearer companies was stated to be under consideration.

In reply to Mr. Channing, Mr. Balfour stated that the Government did not at present contemplate the introduction of legislation having for object to provide that questions dealing with tuberculosis should be dealt with as for the whole country, the better to secure uniformity of administration.

The nursing arrangements in the Egyptian campaign were again the subject of discussion on the initiative of Captain Norton. It was admitted that the principal Captain Norton. It was admitted that the principal Medical Officer of the army of occupation had asked for hospital ship, and that the General commanding in Egypt had promised to consult Lord Cromer and make the application if necessary. No such application, however, was made. The Under-Secretary was fain to contest the advantages of a hospital ship, as if there could possibly be two opinions on such a subject, but he had to admit that considerable delay was entailed by the want of the ship in respect of the 280 men sent home. There were at the hospital base 226 men nurses and 10 women nurses, all trained, for an average of 541 patients. The difficulty of enforcing discipline was alleged as a reason for not increasing the number of female nurses. As this is a matter which closely concerns the comfort and well-being of those who have to do the actual fighting, we may expect it to crop up again, when it is to be hoped the weight of the Government will not be used to prevent the responsibility for short-comings being brought home to the proper parties.

In reply to Captain Norton, Mr. Powell Williams said

there was not the same necessity for establishing convalescent homes for soldiers in Ireland as in England the Irish barracks being mostly situated among small populations and in healthy surroundings. So far as circumstances would permit arrangements would be made for the reception of convalescing soldiers in Ireland similar to those in other parts of the United Kingdom.

In reply to Mr. Strachey, Mr. Chaplin said he had no information to the effect that objections are felt by many medical men at having their patients visited by the public vaccinator. The duty of the public vaccinator to visit the home of an unvaccinated child does not arise until the child has attained the age of between four and five months, unless the parent requests him to visit the home at an earlier date. There is, therefore, ample opportunity for the private practitioner to perform the operation if it is desired.

In reply to Mr. McNeill, Mr. Collings said he had caused inquiries to be instituted concerning the state-ments made at the meeting at Bradford referred to, but

Digitized by GOOGIC

he had been unable to obtain any clear statement of what was actually alleged, nor any evidence of any illegal vivisection being performed by Dr. Hime. He added that the performance upon an animal of an experiment calculated to cause pain without a licence was an ordinary

criminal offence for which any person could prosecute.

In reply to Mr. B. Simeon, Mr. Collings said the Secretary of State had requested the Inspector of Experiments on Living Animals to expedite his annual report as much as possible this year, but no date is fixed for it, and returns to be included in the report are not yet complete.

SIR FRANCIS POWELL obtained leave to introduce a Bill to extend the Infectious Disease Notification Act, 1699, to districts in which it has not been adopted. The Bill was read a first time.

Correspondence

We do not hold ourselves responsible for the opinions of our

THE PROPOSED "LEAGUE OF MERCY."

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIE,-I am hardly disposed to think the Prince of Wales has been wisely advised as to the founding of a "League of Mercy" for the further promotion of his Hospital Fund, which, so far, cannot be said to have achieved great success. The idea of a special order, with all its dazzling tinsel and paraphernalia of grades of Grand Cross Knights down to members ranking the Fifth Class, is inconsistent with, and repugnant to, the cause of charity and the work of philanthropy, which have hitherto escaped evil communications, since it is admitted to be in the interest of charity that the "right hand should not know what the left doeth." This will clearly not be so in connection with this brand new order, as in the printed statement it is said that "founders and benefactors will be eligible for the decoration." doubt the Prince believes that he has taken every precaution in this respect, but the wire-pullers that surround him will take care to make it appear to the public there is something more to be got by subscribers to this fund than has ever before been offered to annual subscribers to the hospitals, and in an indirect manner there will be a proportionate falling off in the direct receipts of the hospitals. Indeed, some of them are complaining that the Prince of Wales's Hospital Fund has had the effect of withdrawing subscribers already; at all events, it has not improved their position. The motives of the Prince in this matter command universal respect, but as one officially connected with hospitals for very many years, I cannot but regret these have been diverted into so questionable a channel. Moreover, it will seem to imply that we all have our price, and herein lies the tempting offer for a higher bid. What has gone before did not go far enough. Agreeing as I do with the remark of one of your lay contemporaries that the motives to which appeal is made by this finery and flummery of a Knight of the Grand Cross of the League of Mercy, "are not those which brought our hospitals into existence, nor will such motives serve to maintain them.

I am Sir, yours truly,

A HOSPITAL SURGEON.

March 4th, 1899.

SALOPHEN IN INFLUENZA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR. SIR,-I happened to notice Dr. Wright's letter drawing attention to the value of salophen in influence in your issue of March 1st, and, with your permission, would corroborate, as the result of practical experience, some of his statements, having used salophen in influenzal cases for over two years. Just as it is difficult to say in a case of rheumatism whether salicylate of soda is more likely to be of service than some other of the commoner anti-rheumatic remedies, so is it difficult, at the present stage of our medical knowledge, to judge in what cases salophen is more likely to prove beneficial than

some of the other drugs in common use for treatment of influenzal symptoms.

The experience which I have had of salophen leads me to believe that its greatest value and efficacy lie in its employment for relief of muscular, gastrie, gastro-intestinal, joint and head pains associated with influenza,

As to its anti-pyretic value I cannot speak highly, as I find that salophen is much more uncertain in action than phenacetin, for example, and the action is more de-layed, and the effect passes off much sooner than when phenacetin is administered.

As affording relief for influenzal headache, especially when associated with giddiness and noises in the ears, salophen in doses of 15 grains, three or four times a day,

is particularly valuable.

Compared with phenacetin, its hypnotic effect, especially in children, is slight. On the other hand, its diaphoretic action is, I believe, greater than phenacetin, antipyrin, or antifebrin, and I have never noticed any depression following upon its administration.

I am Sir, yours truly,

West Hartlepool, March 3rd, 1899.

W. GRAY.

Literature.

STEWART'S PHYSIOLOGY. (a)

THIS is the third edition of a work which promptly conquered for itself a high position in the teaching world. It is not a mere reprint, the work as a whole having been revised and in parts rewritten. A considerable amount of new matter has been added especially in the department of practical exercises. These "practical exercises" constitute the most salient feature of a work which covers some 850 pages, and comprises upwards of 300 illustra-tions with five coloured plates. The author has adopted the plan of "interweaving formal exposition with practical work," On looking over the directions for practical work, one is struck forthwith by the fact that many of the experiments suggested would expose the confiding student to the penalties provided by the law against vivisection, but the author explains that "for various reasons," a somewhat wider range of experiment is open to the student in America than in this country, and English students will have to do many of them by proxy, i.e., learning from demonstrations. The arrangement of the exercises is intended to secure that practical work on a given subject shall actually be going on at the time as it is being expounded in the lectures, obviously an admirable way of securing a proper correlation of theo-

retical and practical knowledge.

A text-book of physiology does not readily lend itself to detailed criticism, especially as the author is not personally responsible for the views and hypotheses therein contained. These have to be grasped by the student without reference to their ultimate fate. Moreover, in regard to the manner in which the subject is treated, for which alone the author can claim credit and incur responsibility, we have nothing but praise. When one compares the work with the text-books from which past generations of medical men gleaned their somewhat perfunctory knowledge of physiology, one is impressed by the progress that has been effected in teaching methods. The proper introduction to the study of a natural phenomenon is obviously an explanation of the mechanical laws which underlie the particular organic manifestation, and that is a rule which the author rigidly adheres to. We cannot adequately comprehend the circulation, unless we have previously acquired a knowledge of the elementary laws which regulate the behaviour of fluids under various and varying conditions and this holds good in respect of all the bodily func-This method constitutes a truly rational and scientific method of teaching such a science as physio-logy, its mechanism being further elucidated, when necessary by reference to the data of comparative phy-

(a) "A Manual of Physiology." By G. N. Stewart. W.A., D. Sc., M.D. Ed, &c. Professor of Physiology in the Western Reserve University, ()leveland, U.S.A., &c. (University Series.) Loadoa: Bailliere Tindall, and Cox. 1892. Pp. 830. With five coloured plates. Price 15s. nett.

siology, a knowledge of which indeed assists the student of morphology. There is, strictly speaking, no such thing as human physiology, the various organs and functions having their counterparts throughout the whole animal kingdom. By such means physiology is lifted out of the category of dry-as-dust sciences, and is invested with an interest all its own. Instead of a series of more or less dubious "facts." we have a series of explanations leading up to certain conclusions which are, to a large extent, capable of actual demonstration. We must congratulate the student on the progress that has been accomplished in this matter, and on the enormously increased facilities placed at his disposal for an acquisi-tion of this special and fundamental knowledge. The volume is clearly printed, tastefully bound, and the illustrations are both numerous and excellent.

SNELL ON THE EXAMINATION OF THE EYE. (a)

This book is likely to meet the requirements of students of ophthalmology, traversing as it does ground which in the past has been too much neglected so far as this special subject is concerned. The author, therefore, in this small manual has made up for the obvious deficiency present in this regard, in the majority of modern text-books on ophthalmic surgery. The work includes chapters on the external examination of the eye, mydriatics and myotics, the ophthalmoscope, testing the sight, abnormalities of refraction, the field of vision, the movements of the eyeball and their anomalies, and simulated blindness - in all of which, in concise and clear language, he gives the necessary details which form the ground-work of the study of eye diseases. In brief, we can strongly recommend Mr. Snell's book, and no dresser in the eye wards of a hospital should be without it.

Medical Aews.

The Medical Sickness and Accident Society.

THE monthly meeting of the executive committee of the Medical Sickness Annuity and Life Assurance Friendly Society, was held at 429, Strand, London, W.C., on 24th ult. In the absence of Dr. de Havilland Hall, the chair was taken by Dr. Major Greenwood, one of the vice-chairmen of the Society, and there were also present Dr. J. B. Ball, Dr Walter Smith, Dr Alfred S. Gubb, Dr. J. W. Hunt, Dr. W. Knowsley Sibley, and Dr. F. J. Allan. As is usual during the early part of the year, a large number of sickness claims are being received by the Society, but not in excess of what is expected and provided for in the table of premiums. The list of those members who are permanently disabled also grows, and as all these are provided by the Society with pensions as all these are provided by the Society with pensions till aged sixty-five, varying in amount from 150 to 50 guineas a year, a considerable sum of money is expended in this manner. This, however, has been specially provided for, and there is every reason to hope that the valuation of the Society's premises, now in progress, will show ample reserves. In 1894, the date of the last valuation, a surplus of £5,000 was returned to the members as cash bonuses. Prospectus and all information on application to Mr. F. Addiscott, secretary, Medical Sickness and Accident Society, 33, Chancery Lane, W.C.

Vital Statistics.

THE deaths registered last week in thirty-three great towns of England and Wales corresponded to an annual rate of 20 8 per 1,000 of their aggregate population, which is estimated at 11,404,408 persons in the middle of this year.

Birkenhead 20, Birmingham 18, Blackburn 32, Bolton 22, Bradford 21, Brighton 18, Bristol 15, Burnley 13, Cardiff 16, Croydon 18, Derby 20, Dublin 30, Edinburgh 26, Glasgow 25, Gateshead 19, Halifax 15, Huddersfield 20, Hull 17, Leeds 18, Leicester 14, Liverpool 26.

London 21, Manchester 25, Newcastle-on-Tyne 20, Norwich 12, Nottingham 17, Oldham 20, Plymouth 22, Portsmouth 15, Preston 21, Salford 22, Sheffield 19, Sunderland 23, Swansea 20, West Ham 15, Wolverhampton 15. The highest annual death-rates per annual 1,000 living, as measured by last week's mortality, were:—From measles, 1'3 in Bolton, and 1 5 in Manchester; from whooping-cough, 1'1 in Bradford, 1'4 in Sunderland, and 2'7 in Birkenhead; from "fever," 1'9 in Blackburn and 23 in Wolverhampton. In none of the large towns did the death-rate from scarlet fever or from diarrhœa reach 1.0 per 1,000. The 103 deaths from diphtheria included 29 in London, 12 in Leeds, 11 in Swansea, 9 in Sheffield, 6 in Liverpool, 5 in Blackburn, 4 in West Ham, and 4 in Birmingham. No death from small-pox was registered in any part of the United Kingdom.

Mortality in Foreign Cities.

The following are the latest official returns, and represent the last weekly death rate per 1,000 of the several populations:—Calcutta 34, Bombay 100, Paris 20, Brussels 21, Amsterdam 15, Rotterdam 19. The Hague 15, Copenhagen 29, Stockholm 24, Christiania 26, St. Petersburg 27, Moscow 24, Berlin 16, Hamburg 17, Breslau 33, Munich 23, Vienna 25, Prague 29, Buda Pesth 27, Rome 18, Venice 32.

Death of Mr. Sargeant, of the Apothecaries Hall, London.

WE have to record the death of Mr. J. C. Sargeant, of the Apothecaries Hall, which took place at Lewisham, on February 27th, 1899, in his eightieth year For nearly forty years he acted in the capacity of Bedell to the Society. Ever kind and courteous, he will long be remembered by former candidates at the Hall. The funeral took place at Lewisham Cemetery, on Thursday last, March 2nd.

DR. WLILIAM HUGHES WILLSHIRE, whose death was announced on Wednesday from syncope, in his 83rd year, was formerly physician to, and lecturer on, the Practice of Medicine at Charing Cross Hospital.

DR. ARTHUR DAVID WHITE, who died on February 18th, at Sidi Omar, Tangier, Morocco, æt. 83 was, at the time of death, the oldest graduate in medicine on the books of Pembroke College, Cambridge, having graduated Bachelor in 1842, Licentiate in 1844, and Doctor of Medicine in 1848.

An Unsuccessful Appeal.

THE dental practitioners of the Manchester district were invited to attend a meeting last week, convened for the purpose of discussing whether the practice of den-Medical Council, as at present, or be transferred to a dental council pure and simple. Some 240 dentists had formally refused the invitation, so that the number of persons present was small, and the meeting was ultimately adjourned to enable the moving spirit in the agitation to draw up his conclusions in more precise form.

Hunyadi Janos Substitution.

A MARSEILLES pharmacist was recently fined 200 frs. and costs for selling a purgative water from a spring called Lozer Janos, of Budaors, Hungary, the same being described on the label as "genuine Janos water." As Hunyadi Janos water is generally known in France as "Eau de Janos," it was held that this constituted illegitimate competition, and the judgment was ordered to be published in a local newspaper.

PASS LISTS.

Royal College of Surgeons, Ireland.

Fellowship Examination.

The following candidates having passed the necessary examination have been admitted Fellows of the College: Mr. I. Knox Denham, L.B.C.S.I., &c., Mr. E. J. Moore, L.B.C.S.I., &c. and Mr. T. G. Stevens, L.B.C.S.I., &c.

The following candidates have passed the primary part of the examination for the Fellowship of the College:-Mr. B. J. Coulter, B.Ch., &c., Univ. Dub.; Mr. J. P. Frengley. B.Ch. &c., Boy. Univ.; Mr. R. D. Joyce, M.B.C.S. Enw., &c.; Mr. C. B. Boyce, Mr. E. Glendy, Mr. P. I. Hanafin, Mrs. H. L. Hennessy, Mr. J. M. S. Levis, and Mr. J. F. Peert.

⁽a) "A Practical Guide to the Examination of the Eye, for Students and Junior Practitioners." By Simeon Snell, F.R.C.S. Edin.; Ophthalmic Surgeon to the Royal Infirmary and to the School for the Blind; Professor of Ophthalmology, University College, Sheffield. With eighty-eight illustrations. Edinburgh and London: Young J. Pentland. 1898.

*A*otices to Correspondents. Short Letters. &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves " Reader, "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

GLYCEBINATED CALF LYMPH.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

Sir,—I think it would be very desirable to find a shorter and more easily pronounced name for Glycerinated Call Lymph, and I propose "Glycalymph," which is shorter by eleven letters and much easer to say, the "y" retaining, of course, its sound in gly-

ceriae.

The descriptive words might be used in full for a few years in the notices to vaccinate, and in a few other cases; but in by far the greater number the word glycalymph would be preferable, and would satisfy all requirements.

Yours faithfully,

J. P. H. Boileau, M.A. M.D.,

Late Brigade-Surgeon Lt. Col. Army Medical Staff.

Trowbridge, Wilts, March 6th, 1899.

MR. B. B. ANDERSON.—We are unable to accede to your request for publication, it not being in accordance with our practice to call in question the discretion of the editor of other journals.

Mr. W.—We must leave to you the responsibility for the views expressed, against which, though we publish, we protest.

M. H. S.—We will make inquiries, and will send our correspondent a private note in the course of a few days.

Mr. Shaw.—It is decidedly unprofessional for a medical man to recommend or prescribe a quack medicine to his patients.

MESSES. POTTER AND CLARE.-The book will be reviewed in due

MR. ERNEST C. CLIFFORD (Anerley).—We do not care to continue a correspondence on vegetarianism. The facts of the case have so often been thrashed out and the matter seems to have become so much one of sentiment rather than reason, that little good can be expected from dishing them up afresh.

Dr. Taylor (Nottingham).—Your very long letter came to hand as we were at press, too late, in any case, for insertion in present number, and too long, we fear, for our next.

Meetings of the Societies and Tectures.

Taylor, E. C., M.D.Lond., F.R.C.S., L.R.C.P., M.R.C.S. Medical Officer for the Workhouse, Parish of St. John, Hampetead.

Weldon, W. F. B., M.A., F.R.S., Linacre Professor of Camparative Anatomy at Oxford, vice Professor B. Lankester.

Whittone, H. M.D., C.M.Edin., Assistant Physician to the Hospital of St. Francis, New Kent Boad, London.

Births.

Anderson.—On March 1st, at East Street, Faversham, the wife of Charles Macdonell Anderson, M.D., M.B.C.S., of a daughter.
Barker.—On March 1st, at Corfe Castle, Dorset, the wife of Toft Barker, M.B.C.S., L.B.C.P.Lond., of a son.
Fuller.—On March 4th, at 7 Oxford Row, Bath, the wife of A. Leonard Fuller, M.R.C.S., L.R.C.P.Lond., of a son.
SHAW-MACKENZIE.—On March 4th, at 31 Grosvenor Street, London, W., the wife of John A. Shaw-Mackenzie, M.D.Lond., of a son and daughter.

Marriages.

Bell-Pereudocer.—On Feb. 28th, at St. John's Cathedral, Hong-Kong, by the Rev. F. R. Cobbold, M.A., Dr. John Bell, Government Medical Department, to Annie Elizabeth, eldest daughter of J. H. Penruddocke, Esq., late H.E.I.C.S., of Winkton, Hants (by telegram).

Green-Yates.—On Feb. 14th, at St. Thomas's, Howrsh, Bengal, Major C. R. M. Green, L.M., F.R.C.S. Eng., to Alice Whitworth, daughter of Robert Yates, Esq., of Bolton, Lancashire.

Morton-Macpherson.—On Feb. 28th, at Christ Church, Bayswater, by the Rev. C. Ridgeway, William Britain Morton, M.D.Lond., of Brislington, eldestson of William Morton, Esq., of Gayles, Yorks, to Louise Elizabeth, daughter of the late Hon. John A. Macpherson, of Melbourne.

Pedley-Wolsey.—On March 1st, at Denmark Place Raptist Chapel, London, Samuel Edward Pedley, M.R.C.S., L.R.C.P., L.D.S., of Camberwell, to Ada Elizabeth, daughter of James Wolsey, of Shelford Lodge, Camberwell.

Beaths.

BERNARD.—On Feb. 25th, at Woodford Green, Essex, Flora E. Bernard, daughter of the late Charles Edward Bernard, M.D.,

Bernard, daughter of the late Charles Edward Bernard, M.D., of Weston-Super-Mare.

Bouron.—On March 5th, at Hove, Brighton, Surgeon-Major John Bouron, M.D., Bengal Army (retired), in his 101st year.

BRENNAND.—Mauch 3rd, at St. Thomas' Home, Westuninster, Sophia, widow of James Brennand, Singapore, and daughter of the late Robert Little, M.D., F.B.C.S.E.,

FORBES.—On Feb. 23rd, Arthur Daniell Forber, M.B., fourth son of the late Dr. Chas. Forbes, R.N., at Horsmonden, Kent, and 23

the late Dr. Chas. Forbes, K.N., at norsmonden, ment, aged 33.

Heath.—On March 2nd, at 248, Brunswick Street, Manchester, F. Ashton Heath, M.R.C.S., aged 69 years.

MCBRIDE.—At Arundell Villas, Weston-super-Mare, suddenly, Alexander McBride, M.D., Fleet Surgeon, R.N., aged 67.

WILLBHIRE.—On Feb. 24th, at Great Marlborough Street, London, W., Wm. Hughes Willshire, M.D., in his 83rd year.

'SAXIN'

Has been aptly termed the "Sweetest thing on earth." It is about 600 times sweeter than sugar and more delicate in flavour. 'Saxin' undergoes no change in the system, and may be safely prescribed in all cases where sugar is harmful.

'Baxin,' 1/4 gr., is supplied in bottles of 100 and 200, at 7d. and 1s. 1d. per bottle.

'EMOL-KELEET'

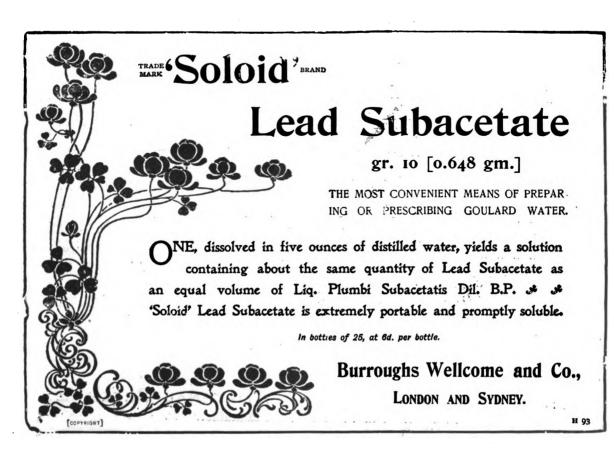

Is a natural powder, containing a large proportion of native silicates. It has proved successful for drying weeping surfaces when all other powders have failed. Its soft, silky texture, soothing influence and other physical qualities enhance its healing action.

'Emol-Keleet' is supplied in neat metal boxes, at 9d. per box.

REPORT

On an Exact Bacteriological Investigation made to ascertain the Value of

"Sanitas" Emulsion

As DISINFECTANTS for GENERAL USE.

By C. G. MOOR, M.A. (Cantab.), F.I.C., F.C.S.,

Member of the Society of Public Analysts, Joint Author of "Applied Bacteriology," &c., &c.

4 DANES INN, W.C., LONDON, July 2nd, 1898.

C. T. KINGZETT, Esq., F.I.C., F.C.S.,

THE "SANITAS" COMPANY, LIMITED,

BETHNAL GREEN, LONDON, E.

DEAR SIR,

1 beg to present you my report on the experimental investigations I have conducted on the preparations manufactured by your firm, named "Sanitas" Oil, "Sanitas" Emulsion, and "Sanitas" Fluid.

The experiments were made to ascertain and establish, if possible, on a scientific basis, the efficiency of these preparations, and their suitability for the purposes for which they are designed as indicated by your publications and labels giving directions for use.

The experiments instituted for this purpose were as follows:—

(a) In the case of the preparations above mentioned, various disease organisms—namely, those of Anthrax, Cholera, Diphtheria, Staphylococcus Pyogenes Aureus and Typhoid were brought into contact with the disinfectant for a given time and in a manner detailed below, and means were taken to ascertain whether the disinfectant employed was sufficiently powerful to determine the death of the organism in a given time.

(b) A second series of experiments was undertaken to ascertain the effect when similar cultures were exposed to different strengths of these disinfectants for a standard time.

(c) Experiments were also made to ascertain the effect on ordinary air, as regards the removal or extermination of organisms suspended in it, by spraying with "Sanitas" Oil and "Sanitas" Tiud.

(b) In the case of "Sanitas" Oil, I have experimented as to the earting of the venous discounted the article of the earting of the venous discounted to the earting of the venous discounted to the earting of the venous discounted to the earticle of the venous discounted to the earting of the venous discounted to the earting of the venous discounted to the earticle of the venous discounted to t

"Sanitas" Fluid.
(b) In the case of "Sanitas" Oil, I have experimented as to the action of the vapour given off at a temperature not exceeding that of the human body.
(c) Finally, I have tried some experiments to ascertain the action of "Sanitas" Oil and "Sanitas" Fluid on the Bacillus of

Plague

TABLE 1. EXPERIMENTS WITH "SANITAS" OIL.

Silk threads infected with cultures of the following organisms were exposed in "SANITAS" OIL for the times shown below and then incubated in broth. Growth is shown by a + sign, no growth by a

Controls all grew well.

I next proceeded to ascertain the strengths of these disinfectants required to ensure the death of the above-named bacteria in a given time—and in the following experiments the time of exposure of the bacteria to the action of the disinfectant was in all cases ten minutes. In these experiments I used the method of shaking together an actively growing broth culture of the organism to be tested, with such a qu-nitly of disinfectant that the resulting mixture contained the strength of disinfectant specified in the tables below; the exact details of the method of experiment are described in Pearmain & Moor's Applied Bacteriology, 2nd Edition, pages 377-382. (Ballière, Tindall, and Cox).

(5). I have made several experiments as to the destruction of bacteria floating in the air of a room by spraying the air with "Sanitas" Oil, and with "Sanitas" Fluid—testing the air by means of

bacteria floating in the air of a room by spraying the air with "Sanitas" Oil, and with "Sanitas" Fluid—testing the air by means of Hesse's tube.

The removal of bacteria from air by spraying will, doubtless, depend very greatly on the mechanical action of the particles of spray, because, as is well known, bacteria are very largely removed from air by a shower of rain, therefore, too much importance must not be attached to such experiments.

Taking, however, the mean of several experiments, whereas the air of the room contained a considerable number of bacteria before spraying, the numbers were reduced, after spraying, to under five per cent. of those previously found.

(6). "Sanitas" Fluid does not give off much vapour at ordinary temperatures; but, Sanitas" Oil, on the other hand, is sensibly volatile at room temperature, and I have tested the action of the vapour given off by "Sanitas" Oil, at blood-heat on bacteria similar to those used in the broth and thread experiments.

Some of the growth from agar tubes was smeared on filter paper and suspended in a wide-mouthed jar containing a little. "Sanitas" Oil. The whole was placed in the incubator (37° C.), and, after an hour, cultures were made on to nutrient media. The result was that only the two most resistant organisms—namely, Anthrax and Staphylolocus Pyogenes aureus—had survived, while Cholera, Diphtheria, and Typhoid failed to grow.

(7). Having a culture of Bubonic Plaque bright by a student from

(7). Having a culture of Bubonic Plague brought by a student from Hong-Kong I tried the effect of "Sanitas" Fluid and "Sanitas" Oil on it. The bacillus was killed in each case by a ten minutes exposure to a strength of 33 per cent. of each disinfectant—the only strength

resided.

In conclusion, I regard the results of my investigation as affording In conclusion, I regard the "Sanitas" preparations are thoroughly reliable, when employed in the strengths and for the purposes specified in the directions issued by the proprietors, while their monpolsonous nature and pleasant character render them applicable in many instances where such substances as carbolic acid or mercurial phoride would be inadmisable or dangeous chloride would be inadmissible or dangerous.

The Lettsomian Lectures

SOME OF THE CLINICAL ASPECTS OF GRANULAR KIDNEY. (a)

By SAMUEL WEST, M.D., F.R.C.P., Assistant Physician, 8t. Bartholomew's Hospital; Senior Physician, Royal Free Hospital, &c.

SYMPTOMS.

Granular kidney may exist for a long time without appearing to affect the health or producing symptoms. When symptoms appear, no matter what, the disease is far advanced and in its later stages. The symptoms are multifarious, and, unless there be intercurrent nephritis, in no way of themselves suggest renal disease, so that they are very misleading, and the true nature of the case is often overlooked.

The symptoms fall into two groups, the cardio-

The symptoms fall into two groups, the cardio-vascular and toxemic. Speaking generally, the symptoms occur in the order in which they are ranged, the cardio-vascular first and the toxemic subsequently, though they may both be present together. The cardio-vascular are important, because they often cause death earlier than might otherwise occur. The toxemic always develop if the patient live long enough. They depend upon the wasting of the kidney, become manifest when it has reached a certain degree, and progress with it pari passu.

degree, and progress with it pari passu.

The cardio-vascular symptoms are more or less mechanical or accidental. The cardiac are summed up in heart-failure. The vascular fall into two groups: the first is formed by hæmorrhage and its results; the second by chronic degenerative affections, especially in the nervous system, the result of imperfect nutrition through the diseased vessel. Heart-failure is often the first symptom to cause anxiety.

failure is often the first symptom to cause anxiety.

These symptoms are usually gradual in onset, but may come on suddenly. The pain, though usually slight, may be severe enough to be called angina. Cardiac symptoms are, however, not constant even where the heart is greatly hypertrophied or the valves diseased. Acute pericarditis belongs rather to the toxemic group, and even where it does not of itself cause death it is a warning that the end is near.

The vascular lesions produce three sets of symptoms: 1, Those due to rupture and consequent hemorrhage; 2, those which result from nutritive disturbances in the parts supplied by the diseased vessels. This is especially met with in the central nervous system and in the eye; 3, besides these it is necessary to refer to aneurysm, and that not only of the small vessels but of the main trunks.

Hemorrhage may take place in almost any part of the body. It is in the brain that its most serious effects are produced. Post mortem statistics prove the remarkable frequency with which granular kidney is found associated with cerebral hamorrhage.

Epistaxis is common, and may be the first symptom of disease and its importance be missed. Even in the young granular kidney must not be disregarded as a cause of repeated epistaxis.

(a) Abstract of lecture delivered at the Medical Society of London on Monday, March 6th, 1899.

Hæmaturia.—The next most important group of cases is that in which blood is found in the urine. This form of hæmaturia has led to frequent mistakes, as, for example, to the diagnosis of calculus in the bladder, for which operation has been suggested and performed. The hæmorrhage is not often copious, but in slight amount it is common and recurrent. Hæmorrhage may also occur from other parts in connection with granular kidney, stomach, lungs, uterus, &c.

In the last stage of granular kidney the patient may pass into an almost hemophilic condition in which slight, though continuous and almost uncontrollable, oozing takes place from various parts of the body, from the gums, nose, tongue, lips, vagina, or from any wound or scratch in the skin.

The next group of cases to which I wish to refer is that in which, as a consequence of arterial disease, degenerative changes result in various tissues; the most delicate of these is the nervous system. To this Gull and Sutton long ago drew attention and the subject has not, since they wrote, received the attention it deserves.

The toxemic symptoms fall into two groups; in the one they are of acute onset and great severity and usually lead rapidly to death. In the other they are of more gradual onset and of longer duration and of less apparent severity, and of a very indefinite character. They are respectively called acute and chronic uræmia; but as the groups stand in strong contrast with one another it would be well if different terms were employed to denote them. For the acute cases, uræmia in its ordinary acceptation might be retained. For the chronic group, on account of its varied and indefinite symptoms, chronic and renal toxemia would be the better term.

Of the three main theories of uramia the third only remains, viz., that which refers the symptoms only to perverted metabolism. According to this theory the poisons are produced in the body, and by processes not differing essentially from those which take place in health. The kidney plays its part only so far as it makes the elimination of the poison defective. Uramia would thus be brought into close relation with other conditions in which the normal metabolism of the body is perverted. Symptoms resembling uramia may arise under conditions with which the kidney may have nothing to do. When, as in uramia, the kidney plays the chief part, it is very tempting to refer uramia to defective internal secretion, for it is certainly not simply due to defective elimination.

If then we are thus led to associate the symptoms of chronic uramia with chronic extractive poisoning, i.e., with the presence of abnormal amounts of extractives in the tissues and the blood, we are tempted to refer the acute symptoms which often develop with so little warning to defective elimination by the kidney, and we might thus associate acute uramia with the condition of the cells in the kidney just as we do in acute nephritis. It is to the chronic toxamic form that most of the symptoms belong which bring the patient suffering with granular kidney under medical observation. They may be of such a kind as to point to almost any part of the

body as the seat of disease rather than the kidney, and may thus lead to frequent errors in diagnosis.

The gastro-intestinal symptoms are often pronounced, and may be very misleading. Obstinate dyspepsia, especially if associated with pain, might suggest ulcer of the stomach, and this might be attributed, if there were much cachexia, to malignant disease. Vomiting is often a source of difficulty, for it is very obstinate, and does not stand in relation to tne taking of food. When to the vomiting retinitis is added confusion with cerebral tumour is only to be expected. Morning vomiting, which is not rare, might suggest pregnancy, and I have seen cases confused with both these conditions.

The symptoms in connection with the bowels are not as a rule so puzzling. Diarrhea is common with any form of kidney disease, but there are cases in which diarrhea is practically the only symptom, extremely obstinate, and almost uncontrollable.

The dyspetic symptoms are often associated with cramps, and cramp leads naturally to the consideration of gout. Gout naturally suggests lead-poisoning, for these three affections, gout, granular kidney, and lead-poisoning, stand in close relation to one another. The close association of chronic lead-poisoning and granular kidney is interesting as supporting the view that granular kidney is the result of the circulation of some toxic substance in the blood, which like lead excites cirrhosis in the kidney with all its results, just as alcohol produces cirrhosis in the liver. On the other hand, it is also possible considering that all persons who work with lead do not develop granular kidney, that the opposite relation may exist, viz., that they suffer so much from lead symptoms just as others do from gout because their kidneys are granular already.

Cachexia.—Patients with granular kidney may for a long time preserve their normal appearance of health, and even when the signs of granular kidney are well marked, but, as a rule, as the kidney disease advances the nutrition suffers greatly. The cachexia of granular kidney is characterised by anemia and asthenia, and to some extent by loss of flesh, but emaciation is rarely carried to that degree which is met with in advanced malignant disease.

It is in connection with the nervous system that some of the most interesting conditions arise. Headache often occurs in such severe paroxysms as to closely resemble migraine. The vomiting is no doubt often central or nervous, for it stands in no relation with food and is frequently periodical. The dyspnœa, which may be paroxysmal, is very often cardiac and occasionally due to bronchitis and emphysema.

Fits are, of course, the common form in which acute uramia manifests itself, but epileptiform convulsions are not rare as one of the early symptoms of the late stage independent of uramia. In connection with fits may be placed the curious attacks of cerebral irritation, which are not at all uncommon. They may take the form of attacks of general nervous irritability, of emotional excitement, or of almost maniacal delirium.

The cases fall into two groups according as there is general ordema or not. (1) Rashes associated with cedema. These are for the most part crythematous in nature, transitory in duration, produce but few symptoms, and when localised have but little clinical importance. Sometimes the rash is of a papular, lichenous character, and is then generally met with on the backs of the thighs and arms. Eczematous eruptions are not at all uncommon, if there be much cedema, where the parts lie in contact with each other.

I have met with erythema in a patient of 42; pityrasis rubra—one in a man of 47, and the other in a woman of 42; dermatitis exfoliativa; a general

eruption. Rashes of this kind in granular kidney seem almost invariably to end fatally.

The symptoms of acute ursmia have by no means that definite and uniform character which seems to be often assumed. The cases really vary very much from one another, almost as much as do cases of so-called diabetic coma. Fits and coma are the two most characteristic symptoms, and yet patients may not have fits, or, at any rate, no marked convulsions, and they need not be comatose. A patient may be comatose without any fits, or at most with but very slight twitching, and the condition may then closely slight twitching, and presents symptoms very much like those met with in acute promaine poisoning. Whatever the form acute ursmia may take, the prognosis is as grave as it can be.

prognosis is as grave as it can be.

If any of the forms has a less grave significance than the others, it is, perhaps, that in which there are epileptiform convulsions, for these uræmic fits end in recovery now and then. The most interesting fact about uræmia in the course of granular kidney is that it may develop so suddenly, and with little or no warring in the midst of appearant health.

warning in the midst of apparent health.

The objects we should have in view in treatment are—1. To prevent the disease getting worse if possible, and to relieve the damaged organ in every way possible. 2. To guard against the accidents specially likely to occur. These are failure of the heart and rupture of vessels. 3. To counteract or relieve symptoms as they arise.

Of drugs I do not know of any more useful than nitrate of pilocarpin given in small doses two or three times a day by the mouth, or in urgent cases subcutem.

There is one noteworthy fact about pilocarpin in chronic renal disease—viz., that it often does not produce the sweating which under normal circumstances and in similar doses it causes, and yet without the sweating its effect is striking.

There remains, however, one line of treatment to which I wish more particularly to refer, for it has not so far been investigated as fully as it deserves—viz., the treatment of chronic renal disease by means of renal extracts. I have already said that there is no positive evidence at present of the existence of an internal secretion in the kidney; yet the cachexia which develops in chronic renal disease is not at all unlike that which is met with in Addison's disease, or even myxcedema.

Granular kidney also presents other resemblances with these diseases in that the grave symptoms do not arise until the organ is very considerably diseased. There can be no doubt clinically that the late symptoms of granular kidney do depend upon the disappearance of the glands, and it is, therefore, not at all improbable that the kidney has an internal secretion, though absolute proof is not yet forthcoming.

I have had two or three cases of the same kind, and in all the result has been the same, viz., an increase in the amount of urine, and an improvement in the general condition. This improvement followed, and appeared to be due to the action of the remedy.

The use of renal substance extracts is still in a purely experimental stage. Judging by the analogy of myxedema, it would be in the cases of chronic renal cachexia only that we should look for striking results, and this requires early and correct diagnosis. In acute uremia there is so little time to act that recourse must be had to other and more active measures.

My choice of granular kidney as my object was inspired by the hope that what had interested me

would prove of interest also to others. I trust I may not have misjudged. I have not hesitated to express my own opinions, even at the risk of appearing egotistic, though I trust with sufficient modesty to escape the charge of dogmatism. On a subject so full of difficult and contentious questions I cannot expect that my views will commend themselves to all. Yet defined opinions challenge criticism, and criticism tends to advance knowledge.

Original Communications.

"VANISHING TUMOURS." (a)

By D'ARCY POWER, F.R.C.S.,
Asst.-Surgeon, St. Bartholomew's Hospital, &c.

In the course of a paper on "Vanishing Tumours," the author applied the term to swellings which disappeared after such slight surgical operations as incision, puncture, or even simple exposure. Such tumours were not to be confounded with phantom tumours for they were real swellings, more often innocent, but sometimes malignant in nature. Mr. Power then proceeded to quote the following cases of vanishing tumours, which had occurred in his own

CASE 1.—A boy, set. 8, was brought to me a few years ago suffering from a large cystic lymphagioma which occupied the whole of the left side of the neck, reaching upwards behind the pinna of the ear, the lobule of which it had invaded, and extending across the middle line in front of the neck. The swelling had been noticed directly after birth and it had been tapped before I saw it about 150 times with a trocar and cannula. It had not undergone much change in size, and though it did not increase proportionately to the growth of the boy, it got no smaller. The tumour consisted of an elastic and slightly lobulated tissue to which the skin was closely adherent. It clearly contained many cysts varying greatly in size and tenderness. With a full appreciation of the difficulties to be encountered I advised that the tumour should be removed, and in due course I extirpated as much of it as lay in the posterior triangle of the neck. The wound healed by first intention and without any trouble except for a sharp attack of lymphangitis about a fortnight after the operation, due to a long railway journey home in the frosty weather.

Five months after the operation the boy had a second attack of lymphangitis in the tumour and in the following month he had a third attack. After each attack the swelling seemed smaller. He was brought to me again nine months after the operation with the information that the tumour had vanished. I examined the neck carefully and found that the left anterior triangle was so soft that the beating of the carotid artery could be clearly felt and there was no trace whatever of the former swelling. I have seen the boy several times since, but there is no return of the tumour and the two sides of the neck are now quite symmetrical.

CASE 2.—This case is an equally remarkable one and does not seem to be easily capable of an explanation. A girl, st. one year and ten months, was admitted into the Victoria Hospital for Children, at Chelsea, under the care of my colleague, Dr. J. W. Carr, on November 1st, 1898. She had been ailing for six months, suffering at first from whooping cough, and afterwards from bronchitis and diarrhea. During the week before her admission to the hospital she had been getting worse, being feverish, sick, and passing dark-coloured and slimy motions which contained

(a) Abstract of paper read before the Harveian Society, March 2nd, 1899.

blood, whilst for the last day or two her mother had noticed that she had been getting yellow. The ward-note states that on admission the child was fairly well nourished, with a pale yellow complexion and yellow conjunctive, the skin of the body generally being rather pale. The liver was enlarged and a little tender, and its edge could be felt about an inch below the costal margin. All the other organs appeared to be healthy. The temperature was 1022 deg. F. Four days later the jaundice was deeper, the abdomen was distended, and the liver was rather larger, for it now reached about one and a half inches below the costal border of the ribs, the upper limit of the liver dulness being on a level with the sixth rib. After an interval of another four days a note was again made that the liver was considerably larger.

And again, on November 15th and 18th, the notes repeat the statement that the liver maintained its large size and that the jaundice was still present. The child was then handed over to the secular arm on November 22nd in the hope that an exploration of the liver might afford her some relief, and on the same day I opened the abdomen in the upper part of the right semilunar line. The liver was much congested, but its surface was perfectly smooth and free from any adhesions. I passed a trocar and cannula deeply into its substance in three different directions as I thought it possible that there might be an hepatic abscess, but blood alone issued from the punctures. The lower border of the liver was then examined, and a cystic swelling was felt which at first I took to be the gall-bladder, for the liver tissue was firmly adherent to it, and was so thin that a part of the cyst projected through it at some distance away from the edge. A closer examination showed that the apparent cyst was in reality part of the small intestine which was so densely adherent to the liver that it was not thought advisable to separate them. The abdomen was closed and the child was said to have suffered very little from the shock, the pulse being almost, if not quite, as good at the end as it was at the beginning of the operation. The temperature fell to 96.2 deg. in the night, and though it rose on the following day it was never more than 100 deg, during the rest of the patient's stay in the hospital. The abdominal wound was quite healed on December 2nd, and it was noted on that day that the liver was not quite so large, and from that date it gradually declined, and on January 17th, 1899, the patient was allowed to get up and was walking a little by herself and on the 24th and was walking a little by herself, and on the 24th as the liver appeared to be of its natural size and the abdomen was quite soft, she was discharged from the hospital.

A third case occurred in a man, æt. 21, with a large and seemingly inoperable tumour situated between the umbilicus and the pubes, and apparently fixed to the pubes. Three months after the tumour had been exposed it had completely disappeared, and the patient had gained a stone and a half in weight. The fourth case occurred in a tailor, æt. 54, who had a well-defined tumour, shown by abdominal section to be adherent to the external abdominal wall, to the stomach and duodenum, and to the under surface of the liver above. The gall-bladder seemed to be surrounded by the new growth, which thus proved quite irremovable and was thought to be malignant. He was examined four months after the operation by many of the surgeons at St. Bartholomew's Hospital, who were unanimously agreed that no tumour could then be felt in his abdomen. A few months later he died in another hospital with all the symptoms of malignant disease in or near the head of his pancreas. A fifth case was that of a man admitted to the Royal Free Hospital, where he was seen by Mr. James Berry, who opened his abdomen to explore a rounded and hard lump as big as a fist, and situated in the region of the pylorus. Some adhesions were broken down, the man made an excellent recovery, and nothing more was seen or heard of the tumour. Mr. Bryant had also described cases of vanishing cysts which he had seen in the breasts of women.

Mr. D'Arcy Power considered that these five cases of vanishing tumour were in all probability innocent in nature and inflammatory in origin. But his sixth case was on the borderline between an innocent and a malignant growth. It occurred in a man, æt. 24, who had received a blow on the top of his head from the flywheel of an engine. A few months after the injury a tumour appeared at the seat of injury. It grew until it attained the size of a sparrow's egg, and then it disappeared. Six or eight tumours subsequently appeared in different parts of the head and then diminished in size. One of the tumours, however, continued to grow until it attained a size of ten inches when it was removed. Microscopic examination showed it to be a fibrosarcoma, and Mr. Morrant Baker, who had charge of the case, gave it the name of "withering sarcoma." Mr. Power also drew attention to the fact that carcinomatous ulcers of very considerable size have been known to heal, sometimes only superficially, the cancerous process continuing beneath the scar, but in some few cases the repair has been complete and permanent. Instances of atrophying scirrhus, are not very uncommon in old and spare people, He also alluded to another class of vanishing tumours: cancers which disappear after the removal of an ovary; hypertrophied prostates which become smaller when a testicle has been cut out, or when the vas deferens has been divided and adenomata of the breast, which vanish as a result of pregnancy and lactation. The cause of the disappearance in these cases is to be looked for in the intimate physiological connection which exists between the organ removed and the part diseased.

Mr. Power considered that many interesting points for discussion arose in connection with vanishing tumours. He raised the question, what would have happened if no operation had been performed? The cystic tumour would probably have shrivelled up in the course of eight or ten years, when it might have become a wen, or it might have disappeared entirely. The enlarged liver, he thought, would have suppurated, and a similar fate seems to have been imminent

in the cases of abdominal swelling.

It was of extreme interest from a purely pathological standpoint to recognise that such apparently causeless swellings might appear and disappear in the body. It indicated that the connective tissue cells of the part were in a very unstable condition, and it is easy to understand that given the necessary predisposition and the exciting cause such a swelling might determine the position of a malignant growth.

The effect of surgical interference in these cases seemed to be identical with that produced by the incision of any inflammatory swelling. Tension is relieved, and a series of complicated physiological changes are set up which end in resolution—changes which seem to be the direct outcome of alterations in the trophic and vaso-motor functions. The older surgeons set these changes in action by bleeding, their successors with improved surgical methods have ceased to interfere with the blood pressure generally, and are content to modify it locally.

Mr Power concluded his paper by decrecating any attempt to remove a tumour locally, when it was in any way possible to eradicate it wholly. He said that modern surgery, based as it is upon pathology, teaches most emphatically that tumours should be removed as completely and as early as possible, and that the more a swelling is thought to be malignant the earlie and more complete should be the removal. But it has happened in these cases of vanishing

tumours that from one cause or another so complete a removal was impossible, and yet by accident or good luck, coupled with some unusual modification of the morbid process, the result obtained was most satisfactory, though the method adopted was in the highest degree unsatifactory if we look to the means rather than to the end.

EAR COMPLICATIONS IN INFLUENZA.

By MACLEOD YEARSLEY, F.R.C.S.,

Assistant Surgeon to the Royal Ear Hospital: Surgeon in Charge of Dept. for Dis. of the Throat, Nose, and Ear, the Farringdon General Dispensary; Hon. Surgeon for Dis. of the Throat and Ear, the Governesses' Home.

THE British Medical Journal for February 25th. 1899, remarks that in the present epidemics of influenza the most common complications are pneumonia and otitis, "the latter being particularly frequent." Since the otitis of influenza is often of a rapidly destructive type, requiring prompt treatment, a few remarks upon it and its varieties may not come amiss to those who come much in contact with influenza.

Influenza may attack an ear hitherto normal and it may light up old troubles which have been for some time dormant. Like other middle-ear inflammations the influenzal forms may be non-suppurative or suppurative. The latter are much more common than the former, as the inflammation is usually so intense that suppuration is inevitable. When, however, suppuration does not occur there often remains a persistent tinnitus which either disappears after several months, or is the forerunner of a middle-ear catarrh with progressive deafness. I have found influenza assigned as a cause of a fair percentage of cases of middle-ear sclerosis, the latter condition being either due primarily to the influenza or following an acute non-suppurative influenzal otitis. I do not, however, remember to have seen a single case of sclerosis traceable to influenza in which there was not also present some nasal or naso-pharyngeal condition which would have acted at the least as a predisposing

The acute otitis of influenza occurs in two types, (1) that coming on at the same time as the primary disease, and (2) that coming on some seven to ten days later. The symptoms of both types are substantially the same, only that in the former the pain is more intermittent and more severe, the duration of the deafness less, and the general prostration greater than in the latter.

The difference between an ordinary attack of acute otitis media and one due to influenza is marked and cannot fail to strike those who have much experience of the two diseases. In an influenzal otitis the pain is much more sudden in its onset and has more of a neuralgic character; it is distinctly intermittent, and its paroxysms are more frequent and last longer during the night. Perforation of the membrana tympani (operative or natural) gives scarcely any relief to the pain, the intensity of which does not correspond to the objective symptoms. The deafness is more gradual in onset than in simple otitis media, but becomes well marked and lasts three or four weeks, or longer. The nervous prostration is great, and there is marked insomnia.

On examination the membrana tympani appears swollen and intensely congested, with, very frequently, punctate or diffused ecchymoses. When perforation occurs it will be found that there is great swelling of the tympanic lining membrane with a special tendency to the formation of granulations and polypi of the flabby, edematous type. This

great tumidity of the mucous membrane explains the marked deafness and the want of relief by Politzer-The discharge which follows perforation may be rarely abundant and purulent, but is more usually scanty, and may remain sero-sanguinolent during its whole continuance.

These acute suppurative inflammations of the middle ear occurring during influenza may take one

of three forms:

1. The distinctive type of hamorrhagic otitis, of which some description has just been given.

2. A primary mastoiditis, due apparently to direct infection and not to extension.

3. A rapid caries and necrosis of the ossicles or mastoid.

Probably all these forms are due to the direct influence of Pfeiffer's bacillus.

The second type enumerated is a very important one, needing, as it does, prompt treatment on account of the tendency to rapid caries and necrosis, with consequent cranial or sinus complications. According to Politzer (a) the form of mastoid process most frequently affected is the "pneumatic," in which there are numerous cells communicating with each other and the antrum by very small openings. These tiny communications become closed by the inflammatory swelling, and a pent-up collection of pus results. Politzer found these abscesses in the middle or inferior segment of the vertical portion of the process, notably in the superficial cells situated under the cortical layer of bone. In most cases the tympanic suppuration had already ruptured the membrane, otherwise the ordinary symptoms of that condition were present. It must, however, be borne in mind that the invasion of the mastoid—antrum or cortical cells—by Pfeiffer's bacillus is not alwaye preceded by a discharge at the external meatus, and therefore, pain in and tenderness over the mastoid should at once be the indication for a careful examination of the tympanic cavity.

The usual symptoms observed in influenzal mastoiditis are as follows:—Local lancinating pain of a radiating character, tenderness on pressure or percussion on the mastoid, local heat, general rise of temperature. There may be bulging of the tympanic membrane and of the posterior superior meatal wall.

The course of influenzal mastoiditis is usually towards rapid destruction rather than resolution and, although it tends occasionally to open externally, its inclination is more towards caries and serious lateral sinus, or cranial complications.

The third type of influenzal otitis is one in which the destructive process is marked, there being rapid caries of the ossicles, caries of the tympanic wall and, when the mastoid is implicated, caries and necrosis

of that process.

Treatment.—The treatment of influenzal otitis requires to be undertaken with care, and before anything is done, the surgeon should, as far as possible, satisfy himself as to the precise condition of the patient. As has been pointed out, pain in the mastoid occurring in the course of an attack of influenza should always be a danger signal to the medical attendant, and he should at once make a careful examination of the ear

so that prompt measures may be taken.

At the onset of an attack of influenzal otitis leeches should be applied promptly, one over the mastoid process and one in front of the tragus. When they drop off bleeding should be encouraged by hot antiseptic fomentations. For the relief of pain hot, dry cotton-wool applications should be used, together with hot instillations of cocaine in a strength of 10 per cent. Any bulging of the membrana tympani should be met at once by paracentesis. This will be disappointing, in most cases, in its effect upon the pain, but it should be done more

with the intention of relieving tension, and for that reason the incision made should be large and free. Ordinary antiseptic treatment should follow, and when the acute stage has subsided granulations and polypi should be removed with the curette, and the tendency to their formation checked by astringent instillations and applications. Bronner (a) has found instillations of nitrate of silver (10 per cent.) to be especially useful in influenzal cases. Until all pain has ceased and the acute congestion has disappeared no attempt should be made to inflate the tympanum either by the Eustachian catheter or by Politzer's method.

THE MEDICAL PRESS.

The severe prostration must be met by careful general treatment, antipyrin and morphia being specially useful. In some cases large doses of quinine appear to have a good effect. The insomnia should to be met by sedatives and hypnotics, of which sulphonal, trional, and paraldehyde seem to give the best results. When the otitis appears during the attack of influenza the patient should be kept in bed, when it comes on later in the disease confinement to one room will suffice, although bed is better.

When influenza attacks the maistoid as above described, and perforation of the tympanic membrane has occurred, leeches and the use of cold or heat by means of ice, Leiter's tubes, or hot antiseptic fomentations should be tried. The application of counter-irritants or blisters should not be employed, as such agents mask the symptoms and confuse the surgeon. Should the intensity of the symptoms not abate in about three days, an operation on the mastoid should on no account be delayed. If the case is first seen several days after the onset of symptoms, no delay should be permitted for the trial of antiphlogistic remedies. Bulging of the posterior-superior meatal wall, nystagmus, changes in the retina, or facial paralysis, should also decide the question of immediate surgical interference. it is found that the abscess is in the superficial mastoid cells, Politzer insists that on no account should any artificial communication be made between them and the antrum (if they do not already com-This axiom is, of course, the opposite of that which holds good in ordinary mastoid cases. The importance of not delaying operation, is accentuated in influenzal mastoiditis on account of the destructive nature of the inflammation, and the tendency to caries and necrosis.

ON SERUM INOCULATION.

By T. R. WOLFE M.D., F.R.C.S.Ed., Melbourne, Victoria.

An edict has just been issued by the Board of Public Health of Victoria that "every dairy cow must be subjected to the tuberculin test, and if shown to be tuberculous is to be at once disused and slaughtered." This edict is in accordance with the report of the British Royal Commission on Tuber-culosis. The mention of Koch's tuberculin has brought to our recollection the incidents which must be fresh in the memory of us all, viz., the proclamation of a discovery for the cure of consumption, the rush to Berlin, the exultation of medical men in all parts of the world over the discovery and its disappointing results. So wild was the enthusiasm during its acute stage that in Vienna, the Professor of Surgery was hooted for excising a scrofulous joint instead of injecting it with the serum. Manufactories established for its production could not cope with the demand, the cry from every part of the inhabited globe being, send us more of the precious fluid. The cures continued merrily, and it was firmly believed that consumption would soon be counted among the diseases that were;

for the serum was not only to cure, but also to diagnose. Then Virchow demonstrated by post-mortem appearances upon victims of the new cure, that, it not only aggravated the disease, but that it gave rise to disseminated tuberculosis, to acute hemorrhagic pneumonia, and to pulmonary cavities. Then almost suddenly came the collapse.

One would have thought that no more would be heard of the new remedy. But it is astonishing how hard superstition dies, when nourished by a cohort of

zealous devotees.

In connection with the general subject of serum inoculation, Sir Charles Gordon's article in The MEDICAL PRESS AND CIRCULAR of December 7th. brings the gratifying intelligence that, in the mother country there, at least, some influential voices were country there, at least, some influential voices were raised against certain prevailing practices based upon dreamy incoherences. I have always thought that, among English-speaking people, the philosophy of common sense is sure to assert itself in the long run. Sir Charles Gordon mentions Pasteur—the father of these systems. In discussing Pasteur's cure for hydrophobia with some of the Professors of the Paris Medical Faculty, I expressed astonishment that such a burlesque on medical science should have been allowed to exist, the bare mention of which would have raised "shouts of inextinguishable laughter" from my old masters and friends, Claude Bernard, Trousseau and the other authorities of that period. Trousseau and the other authorities of that period. Their reply was "We raised our voices in the Academy against it, mais que voulezous? We were told it was unpatriotic, and Messieurs les Anglais have given éclat to the affair by contributing some thousands of pounds to the Institute." Let us glance for a moment at Pasteur's cure for hydrophobia. All we know of hydrophobia is that, demonstrated by Claude Bernard, it is a disease of the brain manifesting itself in a poisonous secreor the orain manuesting itself in a poisonous secretion of the salivary glands. When a dog is attacked by la rage, hyperexcitation of the brain changes the secretion of the salivary glands into a poisonous substance. It is not a blood poison, for when the blood of the rabid dog is inoculated or transfused into a healthy animal, that animal transfused into a nealthy animal, that animal is not affected in the least, while in a blood disease such as glanders, infection immediately follows inoculation. When a rabid dog bites a man there is a risk of it communicating hydrophobia. When it does so, the symptoms of hydrophobia do not set in at once. There is always an indefinite national of insulation intervating between the hite period of incubation intervening, between the bite and the manifestation of the symptoms. Bacteriology has thrown no light upon the nature of the contagium, no particular coccus is associated with the disease, nor have any bacteria been isolated.

Something, however, may be said in favour of Pasteur's treatment. Cases of hydrophobia are extremely rare, and when a person is bitten by a dog there is generally a state of neurasthenia, the result of constant dread, and the mind may become unhinged. The treatment by Pasteur has a beneficial effect by soothing the nervous system, and we may take it for granted that, as a rule, the virus is so attenuated that it can do no harm.

But unfortunately, Pasteurism has produced a therapeutical epidemic to the prejudice of bacteriology and serumtherapy. Bacteriology has teriology and serumtherapy. rendered excellent service to medicine, and will still achieve great conquests, while serumtherapy may yet dominate medical treatment; but they retard the advent of this practical application who rush crude schemes upon the profession.

I hold that each new discovery should be properly tested, and not issued for circulation till it is, like the

Oh! the irony of fate! Christopher Columbus, the discoverer of a new world, was loaded with chains and

imprisoned, as a reward! but now-if one discovers. or imagines that he has discovered, a bacillus, he cries Eureka! and collects a host of adherents, who concoct a serum, and proclaim him a benefactor of his species—sic iter ad astra.

But to return to the compulsory inoculation of cattle with Koch's serum, which according to the Report of the Royal Commission, is still good enough neport of the Koyal Commission, is still good enough for diagnostic purposes. At the Paris Congress on Tuberculosis, August, 1898, it was reported by a Committee that Koch's new tuberculin (T. R.), although free from the lethal properties of the original fluid, nevertheless contained a poison which lowered the heart's action, spread tubercle to the lymphatic glands, and favoured the development of specific inflammation. Moreover, it was also respecific inflammation. Moreover, it was also reported that of the cattle injected for diagnostic purposes from April, 1896, to May, 1898, that of 30,971 animals which did not react to tuberculin the first time, and got a clean bill of health, 4,524, i.e., 14.6 per cent. reacted the following year, or have since become tuberculous. We find it, therefore, necessary to bring the subject under the notice of the British profession to consider whether, with such information before us, we are justified in enforcing inoculation of all animals.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON. MEETING HELD FRIDAY, MARCH 10TH, 1899.

The President, Mr. Langton, in the Chair.

Mr. H. Betham Robinson described a case of HYDATID CYSTS IN THE UPPER LOBE OF THE RIGHT LUNG AND LIVER BOTH SUCCESSFULLY REMOVED.

The patient was a little boy, æt. 6, admitted under his care into St. Thomas's Hospital on June 7th, 1898. There was not anything to note in the previous history. except that for some time he had had a cough. About three years before the abdominal tumour had been first noticed, the size of a marble This had gradually increased without any pain. Up to his admission there had been no suspicion of the cyst in the lung. On examination he was found to have a firm rounded elastic swelling in the right hypochondriac and lumbar regions, reaching almost to the middle line and below regions, reaching almost to the middle line and below the level of the umbilious. There was a rounded nodular projection on its inner side just under the umbilious. The liver dulness began at the seventh rib in the nipple line, and was continued down over the tumour. whole swelling moved with respiration, and it could be grasped between the hands placed in front and behind, and shifted out of the line. The urine was slightly albuminous. His chest on examination showed that the upper part of the right side in front bulged. The percussion note was dull down to the third rib, and dulness was also present high in the axilla and at the apex of the lung posteriorly. Over the dull area in front the breathing was also present high in the axilla and at the apex of the lung posteriorly. Over the dull area in front the breathing was a tubular, and vocal resonance increased, but behind all sounds were diminished. No crepitations were elicited on coughing. There was no elevation of temperature, so the physical signs pointed to a hydatid in the lung. On June 22nd the liver hydatid was operated on by an incision in the lines semilunaris. The liver came well below the costal semilunaris. The liver came well below the costal margin, and a cyst was seen springing from the inferior surface having the gall bladder on its upper surface and left margin. The cyst, having been pushed into the wound, was incised, and the finger was inserted and hooked the cyst well out of the abdominal wound, preventing any contamination of the peritoneum. The hydatid membrane was removed with forceps after about a pint of clear fluid had escaped. The fibrous wall was not interfered with, the cavity was washed out with 1-1000 perchloride of mercury solution. washed out with 1-1000 perchloride of mercury solution,

and the opening almost sutured up with catgut except for a hole for a gauze drain which was brought out of the abdominal wound. By packing the abdominal and cyst wounds were kept as closely apposed as possible. It will be noted that the cyst was not fixed to the abdominal wall. The subsequent progress was uneventful except that the discharge became purulent on the 10th day with a slight rise of temperature. In spite of this the wound was soundly healed at the end of a month and tucked up under the liver. During this time his lung signs underwent no change, but his liver still remained pushed down. A skiagram made by Dr. Berry Blacker showed a well-marked opacity in the upper lobe of the right lung, so dense as to obliterate the rib shadows. On August 15th the lung was operated on. The pectoralis major being split, an inch and a half of the second rib was resected, and then on careful incision it was evident that the pleural layers were adherent. Turning the boy on his right side so as to allow free exit for the fluid and to prevent a possible flooding of his bronchial tubes on the collapse of the cyst, a hollow needle was introduced to get a knowledge of the depth of the cyst from the surface, immediately a drop of fluid appeared, which was about one quarter of an inch in, a free incision was made and several ounces of hydatid fluid gushed out. The finger was introduced and the cyst membrane removed whole with the aid of forceps. The cyst was about the size of an orange, without any daughter cysts. There was fortunately no communication of the fibrous sac with the larger tubes, for there was no marked coughing nor bloody expectoration after the incision, nor from the physical signs afterwards. A large indiarubber drain was introduced. For some few days afterwards he had a high temperature, and physical signs indicative of some localised pneumonia, but without any signs of pleuritic effusion. At the end of ten days his temperature was only slightly raised at night, and the tube was removed and a gauze drain substituted. At each daily dressing the boy was turned on his face so as to thoroughly drain the cavity, which was then insufflated with equal parts of aristol and boracic acid. On September 7th (the twenty-second day) the wound was quite superficial, and the lung on examination was resonant all over, air entering well right down to the base of the lung with expiration, still in places tubular, but no adventitious sounds. On the 9th he got up, and on the 19th, when the wound was quite healed, the lung on examination gave no evidence of any cavity. He went to a convalescent home on September 22nd, and has remained well since.

Dr. Kingston Fowler asked whether the patient had continued in good health, mentioning that he had recently heard of two similar cases successfully operated upon, but in both instances the patient had subsequently

developed pulmonary tuberculosis.

Mr. B. Robinson, in reply, said that up to two months ago at any rate the patient had remained perfectly well. CASE OF PANCREATIC CYST TREATED BY INCISION AND DRAINAGE.

Mr. A. BARKER related the case of a boy, æt. 14, admitted July 12th, 1897. He had had a fall some weeks previously striking his left side. He was rendered unconscious and remained so for some hours, and for a fortnight after he was stated to have been delirous, also to have spit blood several times. A large swelling occupied the left side of the abdomen throughout the left hypochondriac, lumbar and left half of the epigastric and umbilical regions. There was also slight fulness in the right halves of the corresponding regions, especially the umbilical. The swelling came from beneath the left costal margin which was distinctly bulged. The tumour was dull on percussion, and on the left this dulness was continuous with that of the spleen. The tumour moved with respiration. There was apparently a small amount of fluid in the peritoneum. Considering it to be a pancreatic cyst he, on July 15th, 1897, opened the abdomen by a three inch vertical incision through the left rectus muscle close below the ribs. On opening the peritoneum the stomach was found stretched over the tumour and the transverse colon lay below it. Between the two there was a small space through which the cyst was tapped giving issue to three or four pints of fluid, at

first clear and light coloured, but becoming slightly brown towards the end. He sutured the lips of the cyst to the edges of the wound and left in an iodoform gauze drain. The patient did we'l, and left the hospital on August 15th with the wound quite healed. There had been no return of the trouble. A careful analysis by Dr. Nabarro and Dr. Sidney Martin gave the following results:—the fluid was of a brownish-yellow colour, sp. g. 1010, with a sweet aromatic smell, not urinous, reaction alkaline, no sugar or bile, but a trace of peptone. on boiling it gave one-half (3 per cent.) albumen. Total solids 163 per cent.; ash 081 per cent.; total proteids 066 per cent. The fluid displayed marked amylolytic action, but no fat splitting or protolytic action.

Mr. Albam Doran remarked that one could not have

a better clinical subject for surgeons to discuss than this cyst question. The author's paper seemed to clinch what a surgeon ought to do in the surgical treatment other than operating. In reference to the question of diagnosis he remarked that a broad-based cyst, if rather large. he remarked that a production of though fixed to bone or adjacent organ, could, when though fixed to bone or adjacent organ, could, when though fixed to bone or adjacent organ, could, when grasped, be made to move laterally very freely. That had been the case with his own patient. He pointed out that it was exactly the same with a pelvic cyst, which could often be freely moved, although so firmly fixed as to require enucleation. He agreed that the best treatment for pancreatic cysts was incision and drainage. It often happened that the nature of the cyst could not be diagnosed even half through the operation, some-times not till the very end of it, and several of the operators had openly admitted that they would not have done the operation had they known beforehand what it was, the risks being too great. He recalled that Kronlein had successfully removed a cyst, but the patient died on the tenth day, and post-mortem the transverse colon was found to have sloughed. Poncet, who had operated on several cases, did a very bold operation on an almost sessile cyst in which he left seven clamp and pressure forceps sticking out of the wound. One of them when removed was followed by hæmorrhage and had to be hastily reapplied, though it was impossible to see what one was taking hold of. The patient recovered, but it was obvious that in reapplying the forceps he might have grabbed anything. Eves and Nashville had removed a grabbed anything. Eves and Nashville had removed a cyst of the tail of the pancreas which was a comparatively easy situation, yet not only the meso-colon but also the transverse colon were torn across. These were repaired, and the patient recovered, but that was a risk which few of them would be prepared to face. In other cases the splenic vein and artery had been wounded. Evidently therefore the risks of removal were too great if one bore in mind the excellent results of drainage, as in the author's case, in his own and in the three cases of Mr. Bilton Pollard's, reported in the British Medical Journal. The right treatment was not to perform an operative feat but to drain.

The President concurred in the view that drainage was the best treatment. He referred to the case of a gentleman with an enormous tumour in the situation mapped out by the author. It was not an ordinary pancreatic cyst, there being hæmorrhage into the substance of the organ. The patient was from the Sister Isle, and the case was supposed to be one of malignant disease far back. He thought, however, that he could feel fluctuation, but the exact situation of the tumour could not be decided. He made a median incision and went above the stomach through the gastro-hepatic omentum giving issue to 9½ pints of old blood. The patient, although very ill for a few days, did remarkably well with drainage. The interest in the case lay in the fact that three years afterwards he was taken ill and ultimately died, and post-mortem it was found that the portal vein had become so constricted in the scar tissue that there was practically no circulation through the hepatic area.

Mr. ABBUTHNOT LANE mentioned the interesting fact that in one of his cases the cyst, though distinctly pancreatic, was made up of three cysts.

Mr. BARKER, in reply, insisted on the fact that the boy was delirious, a fact which suggested reflection as to the cause thereof. Many cases of multilocular cysts had been recorded, but he was interested to hear that Mr. Lane had dealt with one successfully, a successful result being the exception.

Mr Battle brought forward the account of a case of SUCCESSFUL REMOVAL OF A LARGE MALIGNANT FRONTAL TUMOUR WITH UNDERLYING BONE.

The patient, a married woman, set. 35, was admitted to the Royal Free Hospital on June 21st, 1898. Eight years before a small lump had been noticed in the scalp. a little to the left of the middle line hehind the hair of the frontal region. Several operations had been performed for its removal, and the present growth had been growing for two years. In some months there had been intermittent hæmorrhage from it, and her general health had greatly deteriorated. A large irregular nodular mass with overhanging edges presented in the frontal region. This measured about 3 ins. by 4½ ins., and projected 3½ ins. from the level of the scalp. Vascular and foul smelling it presented a formidable aspect, whilst the removal of the dressings caused troublesome bleeding, which required steady pressure to arrest it. Firmly attached to the bone, it did not pulsate, and was not accompanied with glandular enlargement. January 27th, after the application of an elastic bandage circularly to the head to control bleeding from superficial vessels, the tumour was removed from the surface of the bone, and pads applied to arrest the bleeding which ensued from the skull where the growth had inraded it. This pressure was removed next day. On February 7th the bone affected was removed; a trephine was first applied, and from the opening thus made a circular saw worked by a hand motor was guided so as to divide the bone above and below, after which a few strokes of the chisel were sufficient to free the implicated portion. The growth had not invaded the dura mater, but presented a series of closely set elevations with flattened tops where it had completely eaten away the skull. Very little hemorrhage (comparatively) followed the removal of this piece of bone, but one vessel in the dura mater required the pressure of a pad and a bandage to arrest the bleeding from it. She got up on February 25th. Granulations soon sprang up, and on March 2nd skin grafts after Thiersch's method were taken from the thigh and placed on the dura mater—with full success. She left hospital on March 22nd—greatly improved by her stay. There was then an irregular circle of dead tissue around the area of operation, which gradually separated during the next few months, and cicatrisation took place around. The relief to the patient and the improvement in her general con-dition and annearance are very great. Wearing a dition and appearance are very great. Wearing a handkerchief across the forehead and round the head she is comfortable, and there is no suspicion aroused of the underlying deformity. No attempt has been made to cover over the area left after removal of the bone, by means of a plate. Mr. Battle drew attention to the various methods of removing portions of the skull now available, and Messrs. Down showed instruments adapted to this object during the course of the evening. The rarity of such cases was mentioned, and the unusual character of this fungating growth, the microscopical examination of which showed it to be a sphenoidalcelled carcinoma. The case was also interesting from the fact that it was necessary to apply grafts to the dura mater in order to provide for its better protection from the air.

Mr. BARKER agreed with the author that the motor had very considerable drawbacks being difficult to direct and apt to jam. Possibly with a large fly wheel it might be more practical. He recommended the use of Gigli's wire-saw which he himself had recently used with very satisfactory results. He suggested, however, that instead of the loops, if the ends were shaped like a sound it would be more easy of introduction.

Mr. BATTLE, in reply, said that at the time he did this operation he was not acquainted with Gigli's wire-saw.

Mr. Arbuthnot Lane read notes of a case illustrating an operative procedure for

ERASION OF THE ANKLE-JOINT

which gave a clear field for the complete removal of tuberculous material from this joint without offering some of the objections he had found to arise occasionally in that he described in the "Trans. Clin. Soc," Vol. XXV. In that operation he divided by means of a transverse incision all the structures around the joint except the internal lateral ligament, the tibialis posticus and the flexor tendons of the toes. The divided tendons were carefully sutured, but in spite of this, often owing to infection of the joint previous to operation, they occasionally united imperfectly, and deformity and imperfect control of the foot resulted. Besides the transverse incision through the skin, he now made vertical incisions of sufficient length to enable him to expose the several tendons for a considerable length. In the young infant he found he could expose the interior of the joint by dividing the peroneus tertius alone as well as the external, anterior, and posterior ligaments, the other tendons being turned out of their sheaths and hooked aside. In older children he also divided the peroneus longus and high up, cutting through muscular and tendinous fibres, securing larger and more vascular areas in accurate apposition, and keeping the sutured portion at a distance from the joint and so minimising infection of it. He took the same precaution with the peroneus tertius. By this means the objections to the other operation are practically completely avoided without diminishing its thoroughness.

HARVEIAN SOCIETY OF LONDON.
MEETING HELD THURSDAY, MARCH 2ND, 1899.

Mr. HENRY JULES, F.R.C.S., President, in the Chair.

ME. D'ARCY Power read a paper on "Vanishing Tumours," of which we publish a full abstract elsewhere. The President referred to the case of a woman who had been under his care, in whom both eye-balls were protruding, and there was extensive anæsthesia of the forehead and almost complete blindness. In each orbit an indurated mass could be felt at the outer canthus and below the globe. The growths were believed to be malignant, and a portion of one of them which was removed for microscopic examination presented appearances which were believed to be sarcomatous rather than gummatous. After a few months' treatment with mercury and iodide of potassium, however, the tumours entirely disappeared. They were in all probability gummatous.

Mr. Alban Doban suspected that Morrant Baker's "withering sarcoma" of the scalp was akin to the fibromas of the abdominal wall, a large specimen of which he had himself removed from the sheath of the rectus that very day. They caused danger by their size, but sometimes disappeared spontaneously. Reed, of Cincinnati had reported one case where the tumour seemed irremovable when exposed by the knife; the skin-wound was closed and the tumour, certainly a fibroma, disappeared. Mr. Doran knew of a case where the patient refused operation for what seemed to be a fibroma of the abdominal wall. She became pregnant, and the tumour vanished. The majority of vanishing tumours in the abdominal cavity itself were simply cases of tuberculous peritonitis. When a "cyst" was diagnosed, and a circumscribed collection of serum, bounded by intestine bearing old tuberculous deposit, was laid open by the knife, it was apt to be mistaken for a cyst of the urachus or for a malignant ovarian tumour with metastatic deposits. Even after long experience the surgeon often found such a case very puzzling. But it nearly always got well. Mr. Doran had seen perfect cure follow incision in a large number of cases where he had designedly incised the peritoneum for the relief of tuberculous disease, and also in two instances where he suspected the dense deposit in the parietal peritoneum to be malignant. He had never known improvement to follow exploratory, incision where real sarcoma or carcinoma was detected.

Dr. Cock mentioned the case of an old lady, æt. 71, who was feverish. On examination, a hard mass reaching from the right side of the pelvis to the lower border of the liver, easily defined from side to side, not doughy to the touch, and extremely tender, was discovered, uterus partly fixed and a bloody discharge noted

Purgatives had no effect and there never were any signs of fæcal accumulation. Consultants were of opinion that the mass was carcinomatous. After an illness of ten weeks patient became better, the mass shrank, and at the end of a six months' holiday at the seaside patient returned quite well with no tumour. She ultimately

died five years afterwards from bronchitis

Mr. Eastes referred to the large number of vanishing tumours which were associated with various parts of the organs of generation (male and female), including the female breast. A striking instance was furnished by fibromata of the uterus occurring in middle life He had seen an uterine fibroid (as large as a pregnant uterus towards the end of gestation) disappear almost entirely within a year after cessation of menstruction, and the patient recover health, though previously she had almost died on several occasions from excessive "monthly floodings." But, the vanishing tumours most often seen in general practice were probably fecal accumulations in the colon. One patient, who found aperient remedies always produce pain and consequently neglected them, had twice within the last two years allowed such an accumulation to occur, and passed through a severe illness before she was relieved. She probably had adhesions; at any rate, there was a history of peritonitis in childhood, with constipation ever since. During each of these latter illnesses the cylindrical accumulation in the ascending colon, measuring six inches in length and four inches in diameter, had occupied a fortnight in vanishing, and on several days in that period some ten or twelve distinct hard, almost spherical, masses of fæces were removed by finger, or large enemata from the rectum. The medicine which had accomplished the removal in the last illness was a pill composed of resin podophyll and ext. belladonna, an eighth of a grain of each in each pill, given once twice or thrice daily, according to the necessities of the case
